NATURE

A WEEKLY JOURNAL OF SCIENCE

"*To the solid ground*
Of nature trusts the Mind that builds for aye"—WORDSWORTH

198

Volume 194

APRIL 7, 1962, to JUNE 30, 1962

Part 2

Pure Chemistry Library.
SCIENCE COLLEGE.
92, Upper Circular Road,
CALCUTTA.

INDEX

AARONSON, S , et *al* Occurrence of Arachidonic and Related Acids in the Protozoon *Ochromonas danica*, 1282
Ababei, L., et *al* : Variations in Inorganic Pyrophosphatase and Glutaminase in the Liver and Brain of Mice poisoned by Carbon Tetrachloride, 983
Abercrombie, M., and Jean Brachet (edited by) : Advances in Morphogenesis, Vol. I, *review* by L. J. Hale, 1004
Ability of the Trophoblast to destroy Cancer Tissue (D. R. S Kirby), 696
Abrahamsen, David : Psychology of Crime, *review* by M Grunhut, 46
Absolute Threshold for Electric Shock (R T. Green), 1303
Absorption and Afterglow Spectra of Selenium Dioxide (L. Herman, H. Grenat and J Akriche), 468
Absorption-Elution Grouping of Modifications and Development of Bloodstains (R A Outteridge), 385, *erratum*, 534
Absorption of Radiostrontium by the Gills of Freshwater Fish (I L Ophel and J M. Judd), 1187
Absorption Spectra of the *D*-State Ions $TiCl_6^{-3}$, $TiCl_4^{-}$, $CrCl_4^{-2}$, $FeCl_4^{-2}$ and $CuCl_4^{-2}$ in Chloride Melts (D. M Gruen and R. L. McBeth), 468
Accelerated Collagen Formation and Histamine (N Sandberg), 183
Acceptance of Tumour Homografts by Thymectomized Mice (Carlos Martinez, Agustin Dalmasso and Robert A Good), 1289
Accumulation of a Distinct Macromolecular Component in Rye Embryos as a Result of Vernalization (Joseph Nitsan), 400
Accuracy in Thermogravimetric Analysis (G. M Lukaszewski), 959
Acetate : Electrophoresis of Serum and Soluble Liver Proteins on Cellulose (F. A. Mullan et *al*), 149
Acetylcholine Sensitivity of Rat Diaphragm Maintained in Organ Culture (R. Miledi and O A Trowell), 981
Acetylcholinesterase Activity in *Nitella* (W. D. Dettbarn), 1175
Acheson, Dr. Roy M , et *al* : Effect of Improved Care on the Predicted Adult Height of Undernourished Children, 735
Achromobacter isolated from Soil Oxidation of Anthranilic Acid by a Species of (J N. Ladd), 1099
Ackers, G. K , and R. L Steere . Purification and Separation of Tobacco Mosaic Virus and Southern Bean Mosaic Virus by Agar-gel Filtration, 114
Ackman, R. G. Structure and Retention Time in the Gas-liquid Chromatography of Unsaturated Fatty Acids on Polyester Substrates, 970
Ackoff, Russell L (edited by) Progress in Operations Research, Vol I, *review* by L S. Goddard, 620
Actaea Racemosa L : Vascular Action of Acteina : Active Constituent of (Prof E. Genazzani and L. Sorrentino), 544
Activation Energy and Fractional Order (D D. Eley), 1076
Active Secretion of Oxygen into the Eye of Fish (Jonathan B. Wittenberg and Beatrice A Wittenberg), 106
Action of Chloretone on Reduced Cozymase Oxidation by Cytochrome c (M. Michaelis and S Hashimoto), 680
Action of 3-Hydroxytyramine and some Tryptamine Derivatives on Spinal Neurones (D R Curtis), 292
Activation of Histidine Decarboxylase in Tumour Cells in Mice (G. Kahlson, Elsa Rosengren and Claudia Steinhardt), 380
Actomyosin Systems · Removal of Calcium and Relaxation in (F. Ebashi and S Ebashi), 378
Acute Radiation Injury · Pathophysiological Aspects of the Massive Leakage of Albumin into the Gastrointestinal Tract (G Birke, S -O. Liljedahl, L.-O. Plantin and J Wetterfors), 1243
Adair, Mrs M E., and Dr G R. E Naylor : Serological Heterogeneity of Normal Human Hæmoglobin, 838
Adamec, Otto, et *al* · Use of a Thin Layer of Calcium Sulphate for the Chromatographic Separation of Corticoids, 477
Adams, C E The Mammalian Egg, *review*, 53 , Oogenesis The Storage of Developmental Information, *review*, 618
Adams, R. G , et *al.* : Local Membrane Current in the Outer Segments of Squid Photoreceptors, 844
'Adaption' of a line of Mouse Bone Marrow to an Incompatible Strain (Dr P. L. T Ilbery and S M. Winn), 941
Addison, G. H · Malayan Orchid Hybrids First Supplement, *review* by V. S. Summerhayes, 1208
Adenine in Division of Soybean Cells Interaction of 6-Methylaminopurine and (C O Miller), 787
Adenine Nucleotides on Phagocytizing Guinea Pig Leucocytes . Effect of (Martha Arcos and William C Hill), 574
Adenosine Diphosphate and its reversal : Aggregation of Blood Platelets by (Prof G V R Born), 927
Adenosine Triphosphatase Activity in Dark and Light Cells of Collecting Tubules in the Mammalian Kidney · Histochemical (Max Wachstein and Maire Bradshaw), 299
Adenosine Triphosphatase in the Squid Giant Axon : Sodium-Potassium-activated (Sjoerd L. Bonting and Leo L. Caravaggio), 1180
Adenosine Triphosphate-level and *in vivo* Viability of Erythrocytes . A Direct Relationship between (K. Nakao et *al.*), 877
Adkins, B · Transformers and Generators for Power Systems Their Behaviour, Capabilities and Rating, *review*, 620
Adkins, J E. · Theory of Elasticity, *review*, 125
Adrenal Cytology of South Indian Anurans (A B. Lakshman), 796
Adrenal Glucose-6-Phosphatase : Alterations in Intracellular Distribution induced by Treatment with Adrenocorticotrophic Hormone (Russell Hilf, Charles Breuer and Aleck Borman), 867
Adrenal Medulla . Nerve Endings on Chromaffin Cells in the Rat (R. E Coupland), 310
Adrenaline on the Skeletal Muscle Vessels of Man Analysis of the Vasodilator Effect of (H Ehringer and H Konzett), 1184
Adrenochrome and Noradrenochrome : Ascorbic Acid, Oxygen, and the Disappearance of (S. Roston), 1079
Adrenocorticotrophic Hormone · Adrenal Glucose-6-Phosphatase · Alterations in Intracellular Distribution induced by Treatment with (Russell Hilf et *al*), 867
Adsorption of Proteins on 'Sephadex' (A N. Glazer and Daniel Wellner), 862
Advances in Applied Microbiology, Vol 3 (edited by Wayne W. Umbreit), *review* by J W G Porter, 70
Advances in Catalysis and Related Subjects, Vols. 11 and 12 (edited by D D. Eley, P. W. Selwood and Paul B. Weisz), *review* by F. S Stone, 60
Advances in Enzymology and Related Subjects of Biochemistry, Vol 23 (edited by F. F Nord), *review* by M. J Selwyn, 1210
Advances in Horticultural Science and their Applications. Proceedings of the 15th International Horticultural Congress, 1958 Vol I (edited by Jean Claude Garnard), *review* by G P. Harris, 223
Advances in Morphogenesis, Vol. I (edited by M. Abercrombie and Jean Brachet), *review* by L. J. Hale, 1004
Advances in Ophthalmology, Vol. 11 (edited by E B. Streiff), *review* by J. Gloster, 70
Aedes aegypti to Moist Convection Currents . Response of (R H Wright and F. E. Kellogg), 402
Aerial Photogrammetry : course on, 921
Aeronautical engineering : T V Lawson appointed senior lecturer in, 1226
Aerosols of *B. lactis aerogenes* Spherical Pseudomorphs in (J M. Creasey), 603
Aerospace Research of the United States Air Force and the American Chemical Society : Conference on Electromagnetic Scattering, 821
Aeschynomene tertiara, a Fossil Wood from the Deccan Intertrappean Beds of Mahurzari, near Nagpur (U. Prakash), 314
Ætiology of 'Wet-belly' in Ranch-bred Mink (Dr. C K Gunn), 849
Afferent Cutaneous *C*-fibre Reactivity to Repeated Thermal Stimuli (Ingrid Witt and J P. Griffin), 776
Agar : Repression of Growth of Mammalian Cells under (H Green and K. Nilausen), 406
Agar-gel Filtration : Purification and Separation of Tobacco Mosaic Virus and Southern Bean Mosaic Virus (R L Steere and G K. Ackers), 114
Agar Technique : Antigen-Antibody Bands in the Micro-Double-Diffusion (S Katsh and J Matchael), 1186
Agaricus campestris Strains (*NRRL* 2334, 2335, 2336) as *Beauveria tenella* (Delacroix Siem) : Identification of Purported (Peter Molitoris), 316
Agassiz Medal awarded, 435
Age of Basalt underlying Bed I, Olduvai (G H Curtis and J. F. Evernden), 611 ; (L. S. B. Leakey), 610 ; (G H R von Koenigswald), 611
Age of Deglaciation in the Ruwenzori Range, Uganda (D A. Livingstone), 859
Age of the Cuddapahs, India (U. Aswathanarayana), 566; (R. D. Russell and W. F. Slawson), 565
Ageing and Environmental Manifestations in Pyruvate Metabolism of Rabbit Foetal and Neonatal Liver (Jacques F. Roux, A Dinnerstein and S. L Romney), 875
Aggregation of Blood Platelets by Adenosine Diphosphate and its reversal (Prof. G V. R. Born), 927
Agmon, Dr. I , et *al.*: Influence of Diet on the Incidence of Atherosclerosis, 16
Agrawal, H , et *al.* : Purification of Clover Yellow Mosaic Virus, 408
Agricultural economics : S R. Wragg appointed senior lecturer in, 1226
Agricultural Research Council, 21
Agricultural Research in Queensland, Australia Extension of, 731
Agriculture and Horticulture : Shelter Research in (J M. Caborn), 1130
Agriculture and Land Use in Ghana (edited by J Brian Wills), *review* by B. J Silk, 717
Aguirre, Maria José R., and Julio R Villanueva Preparations of Cell-Walls of Some Fungi, 791
Aharoni, Dr A. · Appointed senior scientist in electronics, 1226
Ahlfors, L. V., et *al.* : Analytic Functions, *review* by J Clunie, 63
Ahmed, K., and J D. Judah · Sodium Transport and Phosphoproteins, 382
Ainis, H. : Antibody Production *in vitro* by Means of a New Perfusion Chamber, 197
Air at Very High Voltages · Spark Track in (T. E Broadbent and A H A. Shlash), 371
Air Force Office of Scientific Research, 73
Airspora by Inhalation Trapping the (Kate Maunsell), 703
Aitken, Prof A C : *The Case Against Decimalisation*, 532
Akriche, J., et *al* : Absorption and Afterglow Spectra of Selenium Dioxide, 468
Alabaster, J. S., and R. L Welcomme : Effect of Concentration of Dissolved Oxygen on Survival of Trout and Roach in Lethal Temperatures, 107
Alaka, Dr. M. . International Co-operation in Outer Space, 237
Alam, S Q., et *al.* Detection and Estimation of Squalene in Leaves, 479
Albemarle Report, 243
Alberty, Prof Robert A , and Prof. Farrington Daniels . Physical Chemistry, second edition, *review* by B J. Moody, 71
Albrecht, W. J., et *al* · Recovery of Microbial Polysaccharide B-1459 with a Quaternary Ammonium Compound, 1279
Albumin into the Gastrointestinal Tract · Acute Radiation Injury : Pathophysiological Aspects of the Massive Leakage of (G Birke et *al.*), 1243
Alder and of *Rhizobium meliloti* B_{12} Coenzyme Content of the Nodules from Legumes (Mark Kliewer and Harold J. Evans), 108
Aldosterone in *Xenopus laevis* · Gonadotrophic Action of (V van der Schyff and H Zwarenstein), 94

INDEX

Alexander, D. McE., and R. C. Woodham : Premature Bursting of Sultana Buds, 206
Alexander, D. Pauline, and D. A. Nixon : Plasma Clearance of *p*-Aminohippuric Acid by the Kidneys of Fœtal, Neonatal and Adult Sheep, 483
Alexander, P., and Moroson, H.: Cross-linking of Deoxyribonucleic Acid to *Protein following Ultra-Violet Irradiation* of Different Cells, 882
Alkali Metal Nitrate Solvents : Determination of Stability Constants in Molten (D. Inman), 279
Alkali Metal Requirements in *Oxidative Phosphorylation* (L. J Opit and J. S. Charnock), 870
Alkaline Phosphatase of *Escherichia coli* and the Inactivation of Tryptophanase (F C Happold), 580
Allen, J. E , and F. Magistrelli : Production of Continuous High-Current Discharges in Gases, 1167
Allen, J. R. L. · Asymmetrical ripple marks and the origin of cross-stratification, 167
Allen, Dr. L. : Appointed lecturer in experimental physics, 1024
Allerup, S. : Changes in Transpiration induced by Ethyl Alcohol, 1193
Allison, Philip : Art in Nigeria, *Man*, February 1962, 339
Allopregnane Single Crystals : Growth of (Dr. Dorita A Norton and Lorenzo Costa), 649
Allotypy in Human Serum · Antigen Polymorphism of a Low-Density Beta-*Lipoprotein* (Dr. B. S Blumberg et *al.*), 656
Alloy, Cu_2MnSb : An Anti-ferromagnetic Heusler (D. P. Oxley et *al*), 465
Alper, Tikvah, *et al.* : Chemical Protection against Alpha-Particle Irradiation, 1245
Alpha-Keratin : Molecular and fine Structure of (D J. Johnson and Dr. J. Sikorski), 31
Alpha-particle Irradiation : *Chemical Protection Against* (*T. Alper et al.*), 1245
Alpha-Polypeptide Chain : An Abnormal Human Fœtal Hæmoglobin with an Abnormal (Prof. Helen M. Ranney et *al.*), 743
Alpine Meteorology : International Congress on, 730
Alteration in the Surface Properties of Soils by Ion Exchange Resins (L. V. Vaidyanathan and O Talibudeen), 897
Alteration of Sporulation in *Aspergillus niger* by Heat and Deuterium Oxide (Thomas R Henderson and James S. Dinning), 498
Alterations in Deoxyribonucleic Acid from Regenerating Rat Liver after X-radiation *in vivo* (R. Foster and Margery F Ord), 883
Altered Lavas from the Floor of the Eastern North Atlantic (D. H. Matthews), 368
Aluminium Whiskers by Vapour Condensation Growth of (D. J. Barber), 272
Aly, F W., et *al* : Inherited Immunologically Atypical Haptoglobin, 1091
Ambrose, Barbara A., and Dr D. Ambrose : Gas Chromatography, *review* by *D H. Desty*, 822
Ambrose, D. : Gas Chromatography Discussion Group, 824
Ambrose, Dr. D., and Barbara A Ambrose : Gas Chromatography, *review* by D. H. Desty, 822
American Chemical Society and the Office of Aerospace Research of the United States Air Force : Conference on Electromagnetic Scattering, 821
American Democracy : Their Dynamic Relation in (Government and Science) (Don K. Price), *review* by R. Brightman, 419
American Geophysical Union Awards, 631
American Institute of Biological Sciences (Teaching Biology in American High School), 242
American Institute of Electrical Engineers et *al.* conference, 1024
American Institute of Physics : Seminar, 140
American Institute of Physics and American Physical Society : Dannie Heineman Prize awarded, 634
American Miscellaneous Society, 138
American Philosophical Society (Annual General Meeting), 240
American Physical Society and American Institute of Physics : Dannie Heineman Prize awarded, 634
American Scientist, March 1962, 733
Amides : Fundamental NH_2 Stretching Frequencies in Amines and (P J. Krueger), 1077
Amines and Amides : *Fundamental NH_2 Stretching Frequencies* in (P. J. Krueger), 1077
Amines in Inorganic Hydrolysis : Use of (I L. Jenkins and J. Robson), 864
Amino-Acid Unbalanced Diet · *Effect of Moderate Low Temperature on the* Accumulation of Liver Fat of Rats fed an Amino-Acid Unbalanced Diet (Akira Yoshida and Kiyoshi Ashida), 484
D-Amino-acid Oxidase Apo-enzyme : Binding Site of Flavin Adenine Dinucleotide combining with Sulphydryl Group of (Kunio Yagi and Minoru Harada), 1179
Amino-Acids as Ice Nucleators · Some (Bernard A Power and Robert F. Power), 1170
Amino-Acids by Circular Paper Chromatography · Separation of (Dr. D. L H. Robinson and Dr G. A. T Targett), 30
Amino-Acids by Melano-Protein Particles of the Harding-Passy Mouse Melanoma · *In vivo* and *in vitro* Incorporation of (M. Karasek and T Hultin), 87
Amino-acids by the fungus *Botrytis fabae* · Uptake of (O T G Jones and W. A. Watson), 947
Amino-Acids in Human Ejaculate by Ion Exchange Chromatography : Determination of Free (G Krampitz and R. Doepfmer), 684
Amino-acids *in Rat Brain* . *Interference* of Chlorpromazine with the Metabolism of Aromatic (K. F Gey and A Pletscher), 387
Amino-acids in the Nutrition of *Shigella sonnei* · Role of Thiamine and (Prof. Mitsuru Nakamura *and* Bonnie L. Pitsch), 359
Amino-acids on DEAE Cellulose Paper : Development Techniques for the Separation of (C S Knight), 91
2-Aminobutane · Control of *Penicillium Decay of Citrus Fruits with* (J. W Eckert and M J Kolbezen), 888
1-Amino-*Cyclo*pentane Carboxylic Acid : Mechanism of Antitumour action of (L. Berlinguet et *al.*), 1082
Amino-phenylisotriazoles · Nitro- (H El Khadem and M H Meshreki), 373
Amlyase : Photometric Method for Estimating (Ejner Nielsen), 89
Ammonia-pH Relationship in Grasses · Inverse (H. F. Birch et *al.*), 1195
Amniotic Ectoderm to Differentiate in Sheep · Competence of the (P. G. Schinckel), 1261
Amniotic Fluid · Oxytocic Lipids in Human (D. F Hawkins), 975
Amphiuma tridactylum : Double Circulation in the Amphibian (Kjell Johansen), 991
Amplitudes of Torsion : Fatigue Failure in Copper Single Crystals at Low and High (H M Bendler and H. D. Nine), 1069
An Abnormal Human Fœtal Hæmoglobin with an Abnormal Alpha-Polypeptide Chain (Prof. Helen M Ranney, Cathleen O'Brien and Alan S. Jacobs), 743
An Antigen in Malignant and in Embryonic Tissues (G. A H Buttle, Jean L Eperon and Eva Kovacs), 780
An Association between Soil Conditions and Dental Caries in Rats (T G. *Ludwig, R S Malthus and W. B. Healy*), 456
An Internal Wave in Lake Nyasa and its Probable Significance in the Nutrient Cycle (D. H Eccles), 832
An *Unusual Parasymbiont of Marine Lichens (T D. V. Swinscow), 500*
Anaerobic Formation of *n*-Hept-1-ene from *n*-Heptane by Resting Cells of *Pseudomonas aeruginosa* (J. Chouteau, E. Azoulay and J C. Senez), 576
Anæsthesia : Effect of Strain and Group Size on the Response of Mice to 'Seconal' (J. H Mackintosh), 1304
Anæsthetics in Rhesus Monkey Tissue · Determination of Volatile (Maynard B. Chenoweth *et al.*), 575
Anæsthetics of Brain Damage due to breathing High-Pressure Oxygen in Mammals : Potentiation by (H. A. S. van den Brenk and Dana Jamieson), 777
Analogues · Partial Synthesis of Vitamin B_{12} Coenzyme and (E. Lester Smith et *al.*), 1175
Analysis of the Vasodilator Effect of Adrenaline on the Skeletal Muscle Vessels of Man (H. Ehringer and H. Konzett), 1184
Analytic Functions (R Nevanlinna, H. Behnke, H. Grauert, L V Ahlfors, D. C Spencer, L. Bers, K. Kodaira, M. Heins, J. A. Jenkins), *review* by J. Clunie, 63
Anaphylactic Histamine Release by 2-Deoxyglucose : *Inhibition of* (Nirmal Chakravarty), 1182
Anaphylaxis : Use of a non-persisting Dye for demonstrating Local (J G. Feinberg and Janet M. Dewdney), 199
Anatomical Society of Great Britain, 74
Anatomy : Dr. A. D Morgan appointed Professor of, 140
Anatomy · Electron Microscopy in (Proceedings of a Symposium), *review* by J. R. Baker, 74
Anatomy of Human Skin Tumour Capillaries (Prof. Frederick Urbach and Dr. James H. Graham), 652
Anatomy of the Monocotyledons. Vol 2. Palmae (Dr. P. B. Tomlinson. Edited by C. R. Metcalfe), *review* by T. G. Tutin, 51
Andersen, P , et *al* : Presynaptic Inhibition in the Cuneate Nucleus, 741
Andersen, P., et *al.* : Presynaptic Inhibitory Action of Cerebral Cortex on the Spinal Cord, 740
Andersen, T , and A. G. Maddock · Evidence of the Influence of Defects on the Szilard-Chalmers Process, 371
Anderson, A. B , and T C. Scheffer : Chemistry of Decay of Heartwood on Ageing in Incense Cedar (*Librocedrus decurrens* Torrey), 410
Anderson, A. F H., and Melvin Calvin Improved Method for the Separation and *Purification* of Chlorophyll *a*, 285
Anderson, M R : Induction of Partial Acquired Tolerance to a Carcinogen, 1290
Anderson, S. G , and J W. Uhr : *The Placenta as a Homotransplant*, 1292
Andres, G. A , et *al* Use of Ferritin-Conjugated Antibody to identify Nephrotoxic Sera in Renal Tissue *by Electron Microscopy*, 590
Androgens : A Possible Ultra-Micro Biodetection Method for (R. R. Cohen), 601
Angiosperms from Lower Permian Coal of the Transvaal . Possible (Edna P. Plumstead), 594
Anglo-American Satellite, Ariel, 432
Ångstrom, Dr A. · Awarded International Meteorological Organization Prize for 1962, 1221
Aniline Poisoning : Effect of Ascorbic Acid in (L. Magos and M Sziza), 1084
Animal Colours : The Nature of (H. Munro Fox and Gwynne Vevers), *review* by E A Spaul, 224
Animal Parasitology · Introduction to (Prof. J. D Smyth), review by Ben Dawes, 1108
Animal Physiology and Behaviour : Rhythmic Activity in (Prof J. L Cloudsley-Thompson), *Vol* 1, *review* by G. P Wells, 1007
Animals · The Nerve of Some (Robert Froman), *review* by B J. G Maitland, 419
Anisotropy Effect in Diffusion under Electric Field (H. J Arnikar), 271
Annual Review of Biochemistry : Vol. 30 (edited by J Murray Luck in association with Frank W. Allen and Gordon Mackinney), *review* by D C. Harrison, 324
Annual Review of Physical Chemistry · Vol. 11 (edited by H. Eyring in association with C. J Christensen and H S Johnston), *review* by J. R. Partington, 71
Annual Rhythm of Wool Growth (J. W. Bennett *et al.*), 651
Anomalous Lorenz Parameter in Specimens of High-purity Copper at Low Temperatures (Dr. M. S. R Chari), 955
Anomalous Spectral Intensity Modification in a Hollow-Cathode Discharge (D. J. Bradley), 967
Anoxia, Cysteamine and a Combination of Anoxia and Cysteamine : Radiation Protection of Tissue Culture Cells by (A. J Vergroesen et *al*), 100
Anoxia : Effect of Pretreatment with Nitric Oxide and *N*-Ethylmaleimide on the Level of Sulphydryl Compounds in Bacteria and on their Sensitivity of X-Irradiation under (John P Lynch and P. Howard-Flanders), 1247
Anoxia · Influence of Uterine Position on the Response of the Mouse Embryo to (D. H. M. Woollam and J W. Millen), 990
Antagonism of Pentobarbitone Anæsthesia in Hamsters by 5,5-Diphenylhydantoin modified by Salicylate (Dr. Peter H Staple and Dr. David J Nutter), 944
Antarctica : Archæocyathine Limestones of (M. Laird and J B Waterhouse), 861
Anthelmintic Properties · *A New Class of Compounds showing* (N C. Brown *et al.*), 379
Anthocyanin Formation . A Possible Link between Root Initiation and (E. P. Bachelard and B. B Stowe), 209
Anthony, H D. : Scientist Who Believes in God, *review*, 67
Anthramine-induced Tumours of the Rat · Interaction between Epithelial and Mesodermal Elements in (Kenneth V. Sanderson), 95
Anthranilic Acid by a Species of *Achromobacter* Isolated from Soil · Oxidation of (J. N. Ladd), 1099

Anti-bacterial Chelating Agents : A Possible Mode of Action of some Anti-fungal and (M. B. Lowe and J. N. Phillips), 1058
Antibodies of Low Molecular Weight in Normal Human Urine (J. S. Remington, E. Merler, A. M. Lerner, D. Gitlin and M. Finland), 407
Antibody Production *in vitro* by Means of a New Perfusion Chamber (H. Ainis), 197
Antibrain Antibodies of the 19S γ-Globulin Type in Rats with Allergic Encephalomyelitis (S. M. Harwin and P. Y. Paterson), 391
Anti-Ferromagnetic Heusler Alloy, Cu_2MnSb (D. P. Oxley, R. S. Tebble C. T. Slack and K. C. Williams), 465
Anti-fungal and Anti-bacterial Chelating Agents : A Possible Mode of Action of some (M. B. Lowe and J. N. Phillips), 1058
Antigen- and Antibody-combining properties and their influence on the immune reaction of red cells (Dr. Harold S. Goodman), 934
Antigen-Antibody Bands in the Micro-Double-Diffusion Agar Technique (S. Katsh and J. Matchael), 1186
Antigen-dependent Stimulation of Synthesis of Deoxyribonucleic Acid in Spleen Cells from Immunized Rabbits (R. W. Dutton and Jennifer D. Pearce), 93
Antigen from *Mycoplasma mycoides* : Enhancement of the Complement Fixation Reaction with a Soluble (G. S. Cottew), 308
Antigen into Antibody-charged Agar in Wintrobe Hæmatocrit Tubes accelerated by Centrifugation : Diffusion of (S. DeCarvalho *et al.*), 1275
Vi Antigen on Bacterial Hæmagglutination and Hæmolysis : Effects of (Prof. E. Neter), 1256
Antigen Polymorphism of a Low-density Beta-Lipoprotein Allotypy in Human Serum (Dr. B. S. Blumberg *et al.*), 656
Antigen : The First Human Blood, —/—, which Lacks the 'D-like' (Philip Levine and M. J. Celano), 304
Antigens in Kidney Microsomes : Tissue-Specificity in the Soluble (T. S. Okada), 306
Antigens of *Brucei* Trypanosomes (K. N. Brown and Dr. J. Williamson), 1253
Antihæmophilic Factor : Conditions influencing the Stability of Human (R. A. Kekwick and P. L. Walton), 878
Anti-Heparin Agents as Inhibitors of Plasma Kinin Formation (Desirée A. J. Armstrong and J. W. Stewart), 689
Anti-Locust Research Centre : Retirement of the director, and appointment of new director, 236
Antiserum : Latex Agglutination Test with Brucella Antigen and (the late Prof. L. Fleck and Z. Evenchik), 548
Antitumour action of 1-Amino-*Cyclo*pentane Carboxylic Acid : Mechanism of (L. Berlinguet *et al.*), 1082
Anti-viral Activities of Several Iodinated Pyrimidine Deoxyribonucleosides (E. S. Perkins, R. M. Wood, M. L. Sears, W. H. Prusoff and A. D. Welch), 985
Anuran Distribution : Zoogeography of Eastern Africa : An Outline Based on (Dr. J. C. Poynton), 1217
Anurans : Adrenal Cytology of South Indian (A. B. Lakshman), 796
Aorta of Animals : Inhibitory Effect of Some Mucopoly-Saccharides on the Lipolytic Activity of the (S. Gero *et al.*), 1181
Aphid Flight Chamber (J. B. Legge), 706
Apparatus for Teaching Science in Schools, 1132
Appeldoorn, J. K., *et al.* : Heating in Capillary Flow, 1067
Appelman, A. W. M., *et al.* : Irradiation Effects on Strand Separation of Deoxyribonucleic Acid, 554
Apple Mosaic Virus : Purification and Serology of Tulare (G. I. Mink and J. B. Bancroft), 214
Apple Trees : A Constant Pattern of Growth in Young (D. H. Maggs), 250
Applied Mathematics : Dr. A. Frankel appointed senior scientist in, 1226
Applied Mathematics : International Dictionary of, *review* by M. J. P. Musgrave, 65
Applied Mathematics : Prof. G. G. Hall appointed to chair of, 1020
Applied Mechanics : Proceedings of Theoretical and, 138
Applied Optics : Special supplement, 1224
Applied Physics : Prof. J. Ring appointed to the chair of, 1222
Approaches to Thermonuclear Power (Dr. R. F. Saxe), *review* by P. F. Little, 1007
Aqueous Humour during the Sexual Cycle of the Rat : Changes in Mucoprotein in Serum and (A. B. Houssay and N. Blumenkrantz), 482
Aquo-Organic Systems : pH Effects in the Radiolysis of (Warren M. Garrison *et al.*), 970
Arachidonic and Related Acids in the Protozoon *Ochromonas danica* : Occurrence of (T. H. Haines *et al.*), 1282
Arachidonite in Liver Fat : Effect of Dietary Linolenate on the Proportion of Linoleate and (Lawrence J. Machlin), 868
Arachnoidal Cell Clusters in Man : Significance of (James Watt), 880
Archæocyathine Limestones of Antarctica (M. Laird and J. B. Waterhouse), 861
Archer, Sir Geoffrey and Eva M. Godman : The Birds of British Somaliland and the Gulf of Aden, Their Life Histories, Breeding Habits, and Eggs, Vols. 3 and 4, *review* by Landsborough Thomson, 1210
Archer, G. T. : Release of Peroxidase from Eosinophil Granules *in vitro*, 973
Arcos, Martha, and William C. Hill : Effect of Adenine Nucleotides on Phagocytizing Guinea Pig Leucocytes, 574
Arion ater rufus L. : Pigment of the Hermaphrodite Gland of (O. Lüsis), 1191
Arley, Niels and Kai Setala : First Scandinavian Symposium on Carcinogenesis, 436
Armstrong, Desirée A. J., and J. W. Stewart : Anti-Heparin Agents as Inhibitors of Plasma Kinin Formation, 689
Arnason, Barry G., *et al.* : Effect of Thymectomy on 'Delayed' Hypersensitive Reactions, 99
Arnikar, H. J. : An Anistropy Effect in Diffusion under Electric Field, 271
Arnstein, Dr. H. R. V., *et al.* : Function of Polyuridylic Acid and Ribonucleic Acid in Protein Biosynthesis by Ribosomes from Mammalian Reticulocytes, 1042
Aromatic Compounds : Conversion of Shikimic Acid to (Pauline N. Morgan *et al.*), 1239
Aromatic Hydrocarbons in Solution : Excimer Fluorescence of (Dr. J. B. Birks and L. G. Christophorou), 442 ; *erratum*, 1128
Aromatic Hydrocarbons : Toxicology and Biochemistry of (Dr. Horace W. Gerarde), *review* by Harold V. Street, 57
Aronson, David L. : *N*-Terminal Amino-Acids formed during the Activation of Prothrombin, 475
Aronson, Dr. L. R., *et al.* : The ATSL : An Observer-to-Computer System for a Multivariate Approach to Behavioural Study, 257
Arousal, Channel-capacity and Decision (Rev. A. T. Welford), 365
Arsenic in Napoleon's Hair : Distribution of (Dr. Hamilton Smith *et al.*), 725
Art in Nigeria (Philip Allison), *Man*, February 1962, 339
Arterial and Tonometric Pressure Measurements in the Eye (R. S. Mackay, E. Marg and R. Oechsli), 687
Arthropod-borne Viruses : Effect of Œstrogenic Hormones on Agglutinability of Chicken Erythrocytes by (A. Salminen), 1301
Ascomycetes : An Introduction to the (British Cup Fungi and their Allies) (R. W. G. Dennis), *review* by E. J. H. Corner, 806
Ascorbic Acid in Aniline Poisoning : Effect of (L. Magos and M. Szíza), 1084
Ascorbic Acid, Oxygen, and the Disappearance of Adrenochrome and Noradrenochrome (S. Roston), 1079
Ascorbigen : Biogenesis of Glucobrassicin, the *in vitro* Precursor of (M. Kutáček *et al.*), 393
Ashby, Dr. Maurice : Introduction to Plant Ecology, *review* by L. M. J. Kramer, 1004
Ashford, J. R. and S. Rae : *Relation between Pneumoconiosis and Environmental Conditions : an Analysis of the Results of the First Series of X-ray Surveys in the National Coal Board's Pneumoconiosis Field Research*, 245
Ashida, Kiyoshi and Akira Yoshida : Effect of Moderate Low Temperature on the Accumulation of Liver Fat of Rats fed an Amino-Acid Unbalanced Diet, 484
Ashida, M., *et al.* : Epitaxial Growth of Condensed Aromatic Polycyclic Compounds, 273
Aspartic Acid Copper Complex by Inoculation : A Total Resolution of (Kaoru Harada and Sidney W. Fox), 768
Aspartyl Residues : A Mammalian Peptidase specific for the Hydrolysis of *N*-Terminal α-L-Glutamyl and (G. G. Glenner *et al.*), 867
Aspergillus niger by Heat and Deuterium Oxide : Alteration of Sporulation in (Thomas R. Henderson and James S. Dinning), 498
Assa, Sara, and Zvi Laron : Immunological Properties of Electrophoretic Fractions of Human Growth Hormone, 491
Assay of Thyrotrophic Hormone in Blood (D. J. El Kabir), 688
Assistance to Agriculture Overseas, 413
Association for Radiation Research and the International Committee for Organizing Congresses of Radiation Research, Congress, 821
Association for the Study of Animal Behaviour, Symposium, 730
Association of Applied Biologists : Election of honorary officers for 1962-63, 533
Association of Consulting Scientists, Election of Officers, 633
Association of Special Libraries and Information Bureaux, Scottish Branch Conference on Preparation of Scientific Reports and Books, 635
Astronomical Dictionary in Six Languages, English/Russian/German/French Italian/Czech (Josip Kleczek), *review* by P. Th. Oosterhoff, 907
Astronomical Works of Thabit B. Qurra (Francis J. Carmody), *review* by Leonard W. Clarke, 49
Astronomy : U.S. Research in Astronomy using High-Altitude Balloons, 1223
Astronomy : Yearbook of, 1962, *review* by D. McNally, 73
Astrophysique : Introduction à (les Étoiles) (Prof. Jean Dufay), *review* by M. R. C. McDowell, 326
Astrup, Tage, *et al.* : Hæmophilia and the Protease Inhibitor in Peanuts, 980
Aswathanarayana, U. : Age of the Cuddapahs, India, 566
Asymmetrical ripple marks and the origin of cross-stratification (J. R. L. Allen), 167
Aterman, K., and S. J. Patrick : Glucose-6-Phosphatase, Glucokinase and Selenium, 195
Atmosphere : Microbiology of the (Dr. P. H. Gregory), *review* by C. T. Ingold, 54
Atmospheric Blow-up at the Auroral Zone (K. D. Cole), 761
Atomic Energy Authority : Nuclear fuel director appointed, 1124
Atomic Physics in Northern Europe, 1227
Atomic Spectra (Dr. H. G. Kuhn), *review* by L. Bovey, 1207
Atomic Weights : New Scale of Nuclidic Masses and (Dr. Edward Wichers), 621
Atoms : Restless Atoms in Solids (Dame Kathleen Lonsdale), 5
ATSL : An Observer-to-Computer System for a Multivariate Approach to Behavioural Study (Dr. E. Tobach, Dr. T. C. Schneirla, Dr. L. R. Aronson, R. Laupheimer), 257
Attenuated Measles Vaccine, 438
Attle, E., *et al.* : Photochemistry of Cellulose in the Far Ultra-violet, 968
Audubon and his Journals (edited by Maria R. Audubon with zoological and other notes by Elliott Coues), Vols. 1 and 2, *review* by Landsborough Thomson, 807

Carty, John J , Medal awarded, 140
Carvalho, A : Variability of the Niacin Content in Coffee, 1096
Case Against Decimalisation (Prof A C. Aitken), 532
Cat Striate Cortex : Regular Impulse Activity of Single Units in the (Gabriel Horn), 1084
Catalysis : The Mechanism of Heterogeneous, congress, 340
Catalysis and Related Subjects : Advances in, *review* by F. S. Stone, 60
Catastrophic Failure of Stressed Polyethylene Terephthalate (R. P. Sheldon), 767
Catch, John R. : Carbon-14 Compounds, *review* by H. Barker, 326
(+)-Catechin in the Rat . *m*-Hydroxyphenylpropionic Acid, a Major Urinary Metabolite of (L A. Griffiths), 869
Catechol : Identification of the Main Ethylenediamine Condensate of Noradrenaline with that of (J Harley-Mason), 684; (T. Nagatsu), 684
Catecholamines in Tissues of the Rat : Intracellular Localization of (Lincoln T. Potter and Julius Axelrod), 581
Causes of Deafness in Schoolchildren : Dr. M E. Barton et *al*., 16
Cawse, P. A., and H J. M. Bowen : Interference by Tungsten with Uptake of Molybdenum by Plants, 399

Cedar (*Librocedrus decurrens* Torrey) : Chemistry of Decay of Heartwood on Ageing in Incense (A. B. Anderson and T. C. Scheffer), 410
Celano, M. J., and Philip Levine : The First Human Blood, —/—, which Lacks the 'D-like' Antigen, 304
Cell and the Organism Essays presented to Sir James Gray (edited by J A Ramsay and Prof V. B. Wigglesworth), *review* by P M B. Walker, 1107
Cell Culture . Mitosis-Stimulating Properties of Embryonic Nucleo-Protein Constituents in (Dr. Roman J. Kutsky and Dr Thomas V. Feichtmeir), 1050
Cell Differentiation and Carcinogenesis (Dr. D Stone), 1039
Cell Differentiation and Interaction (E. M. Deuchar), 1027
Cell Division by Carbon Dioxide · Inhibition of (Constantine Sorokin), 496
Cell Line Derived from Hamster Kidneys · Growth of Foot-and-Mouth Disease Virus in a Fibroblastic (G. N. Mowat and W. G. Chapman), 253
Cell Membrane Structure *in vitro* and its Transformation into an Excitable System : Reconstitution of (Paul Mueller et *al*), 979
Cell Membranes · Electron Microscopic Observations on Rous Sarcoma Virus and (Dr. R. R. Dourmashkin et *al*), 1116
Cell Retention and Incidence of Carcinoma in Several Portions of the Gastro-intestinal Tract (M. Lipkin and H. Quastler), 1198
Cell Turnover in Pulmonary Tissues (H Spencer and R. G Shorter), 880
Celloidin Impression Technique for Recording Egg Sculpturing in *Aedes* Mosquitoes (S Pillai), 212
Cellotriose . Crystal Growth and Cell of (W G. Ferrier), 763
Cells by Anoxia, Cysteamine and a Combination of Anoxia and Cysteamine : Radiation Protection of Tissue Culture (A J. Vergroesen et *al*), 100
Cells · Colchicine-Type Metaphases in HeLa Carcinoma (A. K. Powell), 109
α-Cells in Different Parts of the Pancreas of the Dog · Two Types of Islet (Bo Hellman et *al*.), 1201
Cells of Collecting Tubules in the Mammalian Kidney : Histochemical Adenosine Triphosphatase Activity in Dark and Light (Max Wachstein and Maire Bradshaw), 299
Cells (spleen) from Immunized Rabbits Antigen-dependent Stimulation of Synthesis of Deoxyribonucleic Acid in (R W. Dutton and Jennifer D. Pearce), 93
Cellular Deoxyribonucleic Acid Content · Urea Cycle and (G. W. Brown, Jun.), 1279
Cellular Proliferation Cycle : Effect of Dimethylbenzanthracene on the (J A. McCarter and H. Quastler), 873
Cellulose Acetate : Immunoelectrophoresis with (B. W Grunbaum and L. Dong), 185
Cellulose Acetate Membranes · 'Microspot' Test applied to (Joseph G. Feinberg), 307
Cellulose in the Far Ultra-violet · Photochemistry of (G. S Egerton et *al*), 968
Cellulose Ion-Exchangers Thin-Layer Chromatography of Nucleotides on Layers of (K. Randerath), 768
Cellulose Paper Development Techniques for the Separation of Amino-acids on DEAE (C. S. Knight), 91
Centrifugal Fibres to the Retina in the Pigeon (W. M. Cowan and T. P. S Powell), 487
Centrifugal Fractionation of Wool Wax (E. W. Clark and G F Kitchen), 572
Centromeres, Sites of Affinity and Gene Loci on the Chromosomes of *Saccharomyces* (Prof. Carl C. Lindegren, Gertrude Lindegren, Ernest Shult and Yuh Lin Hwang), 260
Cercariæ : Immunization against Schistosoma japonicum in Rhesus Monkeys produced by Irradiated (H F. Hsu et *al*), 98
Cercariæ of *Schistosoma Mansoni* in Rhesus Monkeys Immunizing effect of Irradiated (Dr S. R Smithers), 1146
Cereal Seedlings by *Puccinia striiformis* · Effects of Pre-Inoculation Host Temperature on Infection of (E. L. Sharp), 593
Cerebral Cortex on the Spinal Cord : Presynaptic Inhibitory Action of (P Andersen et *al*), 740
Cerebrospinal Fluid · Proteins of Central Nervous Origin Present in (Sven J. Dencker and Bengt Swahn), 288
Cerletti, P , et *al*. Potentiation of Narcotic Action by the Brain treated with an Electric Shock, 582
Cerletti, U , et *al*. Potentiation of Narcotic Action by the Brain treated with an Electric Shock, 582
Cern : High-Energy Research at (S Weintroub), 638
Ceruloplasm · Electrophoretic and Immunological Studies on Structural Sub-units of Human (Dr. M D Poulik), 842
Cerulus, F , et *al*. (edited by) . Proceedings of the International Conference on Theoretical Aspects of Very High-Energy Phenomena, *review* by R. G Moorhouse, 73
Cervicovaginal Carcinoma of the Mouse · 5-Nucleotidase Activity In Experimental (M Thiery and R G J Willighagen), 691
Cervix Uteri Orientation of Spermatozoa in Mucus of the (D Tampion and R. A Gibbons), 381
Cestode : Spermatogenesis of a (R A R. Gresson), 397
Chackett, K F Radiochemical Manual, Part I Physical Data, *review*, 1109
Chadwick, Sir James (published under the Scientific Direction of) The Collected Papers of Lord Rutherford of Nelson, O M , F R S , Vol I, *review* by P M S Blackett, 1206
α-Chain of Rabbit Hæmoglobin (Jared M. Diamond and G Braunitzer), 1287
Chain, E. B , et *al* · Structure of Ferroverdin, 769
Chaklin, Dr A , and Dr J Mosbech Cancer Services in Europe, *WHO Chronicle*, 16, No. 3 , March 1962, 538
Chakrabarti, C H., et *al* · Effect of a Concentrate of Rice Polishings on Serum Lipoproteins, 287
Chakravarty, Nirmal · Inhibition of Anaphylactic Histamine Release by 2-Deoxyglucose, 1182
Chalk and the Chalk Rock : Relationships of Fauna and Substratum in the Palæoecology of the (R. E H Reid), 276
Challen, S. B. · Phenolic Alkaloids, 144
Challenger, F : *Obituary* of Prof F Richter, 430
Chang, Prof C C : Outer Van Allen Belts and Neutral points on interface between Solar Wind and Geomagnetic Field, 424
Change in Phenotype associated with the Bacteriophage Carrier State in a Strain of *Proteus mirabilis* (J N. Coetzee and A. O. Hawtrey), 1196
Changes in Absorption during Photosynthesis In the Ultra-violet Spectrum (M Klingenberg, A Muller, P. Schmidt-Mende and H T. Witt), 379
Changes in Endogenous Gibberellins in Relation to Chilling of Dormant Seeds (B. Frankland and P F Wareing), 313
Changes in Metabolic Activities of Hepatoma Cells following Increasing X-ray doses (P. Cammarano), 591
Changes in Mucoprotein in Serum and Aqueous Humour during the Sexual Cycle of the Rat (A B Houssay and N. Blumenkrantz), 482
Changes in the Blood of the Rat induced by the Monocarboxylic Acid of Cyanocobalamin obtained by Fermentation (anti-Vitamin B_{12}). (E Csányi, M. A. Kelemen and J Borsy), 689
Changes in Transpiration Induced by Ethyl Alcohol (S. Allerup), 1193
Changing Scene in University Education (Prof F. C Steward), 420
Chapman, W G , and G. N. Mowat : Growth of Foot-and-Mouth Disease Virus in a Fibroblastic Cell Line derived from Hamster Kidneys, 253
Chargaff, Erwin · Calculated Composition of a 'Messenger' Ribonucleic Acid, 86
Chari, Dr. M. S. R : Anomalous Lorenz Parameter in specimens of High-purity Copper at Low Temperatures, 955
Charlesby, A., et *al* · Radiation Protection with Sulphur and Some Sulphur-containing Compounds, 782
Charlton, T. M. : Progress in Solid Mechanics, Vol I, *review*, 60

Chatagner, Fernande, and Odile Trautmann 'Soluble' Cysteine Desulphurase of Rat Liver as an Adaptive Enzyme, 1281
Chatterjee, Amala . Diffusion Studies of Bovine Serum Alumin with Jamin interference Optics and Microdiffusion cell, 1053
Cheesman, E. E. . Banana Diseases, including Plantains and Abaca, *review*, 223
Chelating Agents A Possible Mode of Action of some Anti-fungal and Anti-bacterial (M. B. Lowe and J N Phillips), 1058
Chelating Agents . Non-Dissociability of the Metal Component of D-α-Hydroxy Acid Dehydrogenase by (Dr. Terenzio Cremona and Dr. Thomas P. Singer), 836
Chelonian Fragments from Makapansgat : Some Fossil (D G Broadley), 791
Chemical engineering . Dr. C. W Nutt appointed reader in, 1024
Chemical pathology Dr. K. Fotherby appointed reader in, 18
Chemical Protection against Alpha-Particle Irradiation (Tikvah Alper, D. K. Bewley and J. F. Fowler), 1245
Chemiluminescence and Oxidation (R. F Vassil'ev and A. A. Vichutinskii), 1276
Chemistry : History of, Vol 2 (Prof. J R. Partington), *review* by John Read, 222
Chemistry · R. C. Seymour appointed senior lecturer in, 1226
Chemistry of Decay of Heartwood on Ageing Incense Cedar (*Librocedrus decurrens* Torrey) (A. B. Anderson and T C. Scheffer), 410
Chemistry of Lignin · The (Supplement Volume 1949-1958) (F. E Brauns and D A Brauns), *review* by J Luckins, 61
Chemotaxis in *Myxococcus* (Anne McVittie and Stanley A Zahler), 1299
Chenoweth, Maynard B , et *al* Determination of Volatile Anæsthetics in Rhesus Monkey Tissue, 575
Cherry, B. W : Elected to a junior research fellowship, 1226
Cherry, R. D , and B W Schroeder Cæsium-137 in the Seas off the Cape of Good Hope, 669
Cherwell (Viscount), The Prof In Two Worlds. The official life of Professor F. A. Lindemann (The Earl of Birkenhead), *review* by R V Jones, 1107
Chessin, M , et *al* · Purification of Clover Yellow Mosaic Virus, 408
Chester, Dr. G. V. . Appointed reader in mathematical physics, 1024
Chick Embryo : Effect of 3-Methylcholanthrene Crystals and Solutions on the Chorioallantoic Membrane of the Developing (P C Beohar and Paul Goldhaber), 879
Chicken Leukæmic Cells : Sex Chromosomes as Markers in Transplanted (Jan Pontén), 97
Children's Cancer Dependent on Climatic Factors (Dr. Denis Burkitt), 232
China, W E · Insects of the Pacific and Antarctic Area, 1230
Chinese Medical Journal (No. 1, 1961) : Attenuated Measles Vaccine, 438
Chlamydomonas Reinhardi · Pure Mutant Clones induced by Ultra-Violet Light in the Green Alga, (Nicholas W Gillham and Prof R. P. Levine), 1165
Chlamydomonas Species · Effect of Polyvinyl Alcohol on (B Czeczuga and H Fr. Nowak), 501
Chlorella · Biochemical Contributions to the Taxonomy of the Genus (E. Kessler and C. J Soeder), 1096
Chloretone on Reduced Cozymaze Oxidation by Cytochrome c . Action of (M. Michaelis and S Hashimoto), 680
Chloride Melts : Absorption Spectra of the *D*-State Ions $TiCl_4^{-3}$, $TiCl_4^-$, $CrCl_4^{-2}$, $FeCl_4^{-2}$ and $CuCl_4^{-2}$ in Chloride Melts (D M. Gruen and R L. McBeth), 468
Chloronitrobenzene Genetic nature of tolerance of *Hypomyces Solani F Cucurbitae* to Penta- and Tetra- (S. G Georgopoulos), 148
Chlorophyll *a* · Improved Method for the Separation and Purification of (A. F. H Anderson and Melvin Calvin), 285
Chlorophyll *c* from *Sargassum flavicans* · Purification of (S W Jeffrey), 600
Chloroplasts : Differences in the *p*H Optimum of the Photosynthetic Fixation of Carbon Dioxide in Isolated Whole and Broken (Helmut Elbertzhagen and Otto Kandler), 312
Chloroplasts · Vitamin K_1 in (L P Kegel and F L. Crane), 1282
Chlorpromazine with the Metabolism of Aromatic Amino-acids in Rat Brain · Interference of (K. R. Gey and A Pletscher), 387
Cholesterol in the Larval Diet on Ovarian Development in the Adult House-Fly : Effect of (W. E Robbins and T J Shortino), 502
Cholinergic Sympathetic Function · Morphological Correlate to a (Folke Sjoqvist), 298
Chondrites · Life-forms in Carbonaceous (Ronald Pearson), 1064
Chondrules and the origin of the Terrestrial Planets (Dr. John A Wood), 127
Chopra, K L , and R. Brill · Electron Distribution and Characteristic Temperature Variation at low Temperatures in Magnesium and Ruthenium, 173
Chouteau, J , et *al* · Anaerobic Formation of *n*-Hept-1-ene from *n*-Heptane by Resting Cells of *Pseudomonas aeruginosa*, 576
Chowdhury, T K R., et *al* . A New Vertebrate Fauna from the early Jurassic of the Deccan, India, 755
Christensen, B Chr , and B Buchmann (edited by) : Proceedings of the Third International Congress on Photobiology (Copenhagen) 1960, *review* by J A V. Butler, 53
Christensen, C J (edited by) : Annual Review of Physical Chemistry, Vol. 11, *review* by J. R. Partington, 71

Christophorou, L. G., and Dr. J. B. Birks : Excimer Fluorescence of Aromatic Hydrocarbons in Solution, 442, *erratum*, 1128
Chromaffin Cells in the Rat Adrenal Medulla : Nerve Endings on (R. E. Coupland), 310
Chromaffin Granules in Human Skin : Staining Characteristics of (L. R. Matz and S. L. Skinner), 585
Chromatium-Strain D Cells with 'Normal' Bacteriochlorophyll Absorption Peaks in the 800-850 mμ Region : Strongly Carotenoid-Deficient (E. C. Wassink and G. H. M. Kronenberg), 553
Chromatographic Reviews : Progress in Chromatography, Electrophoresis and Related Methods, Vol. 3 (edited by Michael Lederer), *review* by R. Consden, 71
Chromatographic Separation of Corticoids : Use of a Thin Layer of Calcium Sulphate for the (Ján Matis *et al.*), 477
Chromatography : Determination of Free Amino-Acids in Human Ejaculate by Ion Exchange (G. Krampitz and R. Doepfmer), 684
Chromatography : Iodine as a 'Non-Destructive' Colour Reagent in Paper- and Thin-layer (G. C. Barrett), 1171
Chromatography of Steroids (Prof. I. E. Bush), *review* by E. Kodicek, 417
Chromosomes as Markers in Transplanted Chicken Leukæmic Cells : Sex (Jan Pontén), 97
Chromosomes in a Marsupial (*Potorous tridactylis*) Tissue Culture (K. H. Walen and S. W. Brown), 406
Chromosomes of *Saccharomyces* : Centromeres, Sites of Affinity and Gene Loci on the (Prof. Carl C. Lindegren, *et al.*), 260
Chromosomes of the Fungus *Cyathus* (Benjamin C. Lu and Harold J. Brodie), 606
Chromosomes of Two Cases of Human Chronic Myeloid Leukæmia (P. H. Fitzgerald), 393
Chrysomelidae (Coleopt.) of China and Korea, Part I (J. L. Gressitt and S. Kimoto), *review* by B. J. Selman, 69
Churchill, D. M., and W. A. S. Sarjeant : Fossil Dinoflagellates and Hystrichospheres in Australian Freshwater Deposits, 1094
Churchill, Ethan D., and Prof. Herbert C. Hanson : The Plant Community, *review* by L. M. J. Kramer, 1004
Chymotryptic Proteolysis : Borate Inhibition of (Samuel H. Eppstein), 1177
Ciba Foundation, Annual Report, 1961, 532
CIBA Lectures in Microbial Biochemistry, Vol. 4, 70
Cichlids : 'Egg-dummies' as Natural Releasers in Mouth-breeding (W. Wickler), 1092
Cigna, Dr. A., and Dr. C. Polvani : Intake of Iodine-131 from milk in Italy during the period October-December 1961, 1123
Circular Paper Chromatography : Separation of Amino-Acids by (Dr. D. L. H. Robinson and Dr. G. A. T. Targett), 30
Citrulline in Proteins : Occurrence of (Dr. G. E. Rogers), 1149
Citrulline Peptides : Biologically Active (Miklos Bodanszky *et al.*), 485
Citrus Fruits with 2-Aminobutane : Control of Penicillium Decay of (J. W. Eckert and M. J. Kolbezen), 888
City Museum, Sheffield : Annual report 1960-61, 919
Civil Science : Committee for the promotion of, 1126
Clare, J. D. : Short-range Guided Weapons, *review*, 1007
Clark, B. F. C., and D. M. Brown : Structure of a Monophosphoinositide from Brain, 1081
Clark, E. W., and G. F. Kitchen : Centrifugal Fractionation of Wool Wax, 572
Clark, George B. (edited by) : Proceedings of an International Symposium on Mining Research, Vols. 1 and 2, *review* by W. G. Thomas, 1006
Clarke, Dr. K. U., and P. Langley : Factors concerned in the Initiation of Growth and Moulting in *Locusta Migratoria* L., 160
Clarke, L. W. : Astronomical Works of Thabit B. Qurra, *review*, 49
Clarke, R. W. : Interpretation of 'Surface Brightness' Measurements of Radio Sources, 171
Clarricoats, Dr. P. J. B. : Microwave Ferrites, *review* by A. L. Cullen, 72
Classification and Nomenclature of Enzymes and Coenzymes (Prof. R. H. S. Thompson) (1229, March 31), *erratum*, 730
Classification of Living Animals (Lord Rothschild), *review* by Isabella Gordon, 50
Clauser, Francis H. (edited by) : Symposium of Plasma Dynamics, *review* by P. F. Little, 73
Clay-Organic Complexes : Stepwise Hydration of (H. van Olphen and C. T. Deeds), 176
Clay, S. : Seed Preservation and Longevity, review, 51
Clayton, Col. P. A. : *Obituary* by G. W. Murray, 528
Clemow, J. : Short-range Guided Weapons, *review* by J. D. Clare, 1007
Clinoptilolite : Cæsium-sodium Ion exchange on (Dr. Calen R. Frysinger), 351
Clonal Propagation as a Practical Means of Exploiting Hybrid Vigour in Rice (R. H. Richharia), 598
Clouds : Polarization of the Light from the Magellanic (R. D. Wolstencroft), 1066
Cloudsley-Thompson, Prof. J. L. : Rhythmic Activity in Animal Physiology and Behaviour, Vol. I, *review* by G. P. Wells, 1007
Clough, Dr. R. W. : Elected to Fellowship, 534
Clover Yellow Mosaic Virus : Purification of (H. Agrawal *et al.*), 408
Clow, H. : Very low Coercive Force in Nickel-Iron Films, 1035
Clunie, J. : Analytic Functions, *review*, 63
Clyne, M. A. A. : Elected to a fellowship, 1226
Coal and Petroleum, 1125
Coal in Electric Power Generation : Position of, 1205
Coal of the Transvaal : Possible Angiosperms from Lower Permian (Edna P. Plumstead), 594
Cobbold, Dr. A. F. : Appointed reader of experimental physiology, 18, 1024
Coccolith Formation (E. Paasche) (193, 1094), *erratum*, 1024
Coconut Soils of the Humid Kerala Coast through Monsoon Precipitations : Nutrient Enrichment of the (K. Vijayalakshmi and K. M. Pandalai), 112
Codling Moth by Gamma-Irradiation : Sterilization of the (M. D. Proverbs), 1297
Coenzyme and Analogues : Partial Synthesis of Vitamin B_{12} (E. Lester Smith *et al.*), 1175
Coenzymes : Classification and Nomenclature of Enzymes and (Prof. R. H. S. Thompson) (1229, March 31), *erratum*, 730
B_{12} Coenzyme Content of the Nodules from Legumes, Alder and of *Rhizobium meliloti* (Mark Kliewer and Harold J. Evans), 108

Esso Magazine, Winter, 1961/62, 141 , Spring 1962, 1132
Esso Review for 1961, 1126
Establishment of Sigatoka Disease of Bananas in the Greenhouse (Roger D. Goos and Marylou Tschirch), 887
Estimation of Metal Content in Nickel Soaps by Polarography (Wahid U. Malik and Rizwanul Haque), 863
Estimation of the Levels of Cæsium-137 in Sea-water by the Analysis of Marine Organisms (Rinnosuke Fukai and Noboru Yamagata), 466
Etch Pits after Polymorphic Transformation : Thermal Formation of (S W. Kennedy and J. H Patterson), 1072
Ethanol-2-^{14}C by Pea Slices Utilization of (E A Cossins), 1095
Ethyl Alcohol . Changes in Transpiration induced by (S. Allerup), 1193
Radiation Effects on Zinc Oxide Catalyst in Dehydrogenation of (M Donato), 969
Ethyl Chlorophenoxyisobutyrate : Modification of Metabolism and Distribution of Lipids by (J M Thorp and W S Waring), 948
Ethylene Hydrogenation . Mechanism of (Charles M Selwitz), 178
Ethylene Production by Sub-Cellular Particles from Tomatoes (G. Ram Chandra and Prof. Mary Spencer), 361
Ethylenediamine Analysis for Norepinephrine Increased Sensitivity of (Herbert Sheppard and Joseph Zimmerman), 578
N-Ethylmaleimide on the Level of Sulphydryl Compounds in Bacteria and on their Sensitivity to X-Irradiation under Anoxia Effect of Pre-treatment with Nitric Oxide and (John P. Lynch and P. Howard-Flanders), 1247
4-Ethylsulphonylnaphthalene-1-Sulphonamide : Tumour-promoting Action of (K P Sen Gupta), 1185
Ettlinger, G , and A Elithorn Transfer between the Hands of a Mirror-Image Tactile Shape Discrimination, 1101
European Launcher Development Association, 531
Euryhaline Euglenoid Flagellates (Gordon F. Leedale), 1133
Evans, A M , and R J King : Palygorskite in Leicestershire, 860
Evans, Harold J , and Mark Kliewer B$_{12}$ Coenzyme Content of the Nodules from Legumes, Alder and of *Rhizobium meliloti*, 108
Evans, Dr Hugh D. Radiochemical Research Laboratories and the Law, 808
Evans, I A , and R M Howell . Bovine Bracken Poisoning, 584
Evans, R A., and D. A. Stansfield : Gastric Esterases of Pigs (*erratum*), 140
Evenchik, Z., and the late Prof L Fleck . Latex Agglutination Test with *Brucella* Antigen and Antiserum, 548

Evernden, J F, and G. H. Curtis : Age of Basalt underlying Bed I, Olduvai, 611
Evidence for a Particular Base Alteration in Two T4 Bacteriophage Mutants (Dr. Jane K Setlow), 664
Evidence from Model Peptides relating to the Denaturation of Proteins by Lithium Salts (J. Bello and H. R. Bello), 681
Evidence of the Influence of Defects on the Szilard-Chalmers Process (T. Andersen and A. G. Maddock), 371
Eviscerated Carcass Fat of Adult Male Albino Mice Visceral and (Levon G. Babikian), 697
Evison, F. F. : Rock Magnetism and Low-angle Faulting, 644
Evolution und Hominisation. Festschrift zum 60. Geburtstag von Gerhard Heberer. Herausgegeben von Gottfried Kurth, *review*, 906
Ewald, Prof. P. P. : First Bragg Lecture, 730
Exchange Programme in Nuclear Science (brochure), 15
Excimer fluorescence of aromatic hydrocarbons in solution (Dr. J. B. Birks and L. G. Christophorou), 442 ; *erratum*, 1128
Excystation of *Eimeria Arloingi* (Marotel, 1905) : Stimuli from the Host Sheep (A R B. Jackson), 847
Exhaust from Diesel-powered vehicles, 19, 532
Existence of an Erythropoietic Labile Iron Pool in Animals (Dr Myron Pollycove and Dr. Mohammad Maqsood), 152
Existence of Gaseous Sulphides of the Transition Elements : Dissociation Energy of Gaseous MnS (R Colin, P Goldfinger and M Jeunehomme), 282
Expansion of the Universe (G S. Hawkins), 563
Expenditure by Colleges of Advanced Technology in Britain, 1021
Experiment in Examining First-year Chemistry Students, 142
Experimental Evidence for Regeneration following Spinal Section in the Minnow (*Phoxinus phoxinus* L.) (E. G Healey), 395
Experimental Lathyrism in Turkey Embryos (J. Malcolm Cameron), 210
Experimental Oxidation of Hæmoglobin Effects of Irradiation in Rats (W. K. Metcalf), 783
Experimental physics Dr W Ehrenberg appointed Professor of, 140
Experimental physiology : Dr A. F Cobbold appointed reader in, 1024
Experimental Production of Spermatic Granuloma in Rats (Joan Mullaney), 487
Experiments for Young Scientists (Don Herbert), *review* by D. C Price, 419
Explosives. Heat Pulses at Initiation of Liquid (C. H Johansson), 83
Export Council for Europe, 137
Export Marketing, 536
Extension of Agricultural Research in Queensland, Australia, 731
Eye : Arterial and Tonometric Pressure Measurements in the (R. S Mackay *et al*), 687

Physiological Disposition and Fate of Nicotine labelled with Carbon-14 in Mice (C. G Schmiterlow and E. Hansson), 298
Physiology : Dr. J N. Hunt appointed to the chair of, 435
Physiology (experimental) Dr A F. Cobbold appointed reader in, 18
Phytic Acid as a Phosphorus Reservoir in the Developing Potato Tuber (B. Samotus and S Schwimmer), 578
Phytohæmagglutinin on the Morphology of Cultured Leucocytes · Effect of (Michael W. Elves and John F. Wilkinson), 1257
Piala, J J , *et al.* : Biologically Active Citrulline Peptides, 485
Piazza, M , *et al* : Interrelation between Tryptophan and Nicotinic Acid in Human Viral Hepatitis, 976
Piddington, J. H. · Cosmic Magnetic Fields, 962
Piel, Gerard : Science in the Cause of Man, *review* by The Very Rev. Marcus Knight, 512
Pierce, T. B., and P. F. Peck Use of Di-(2-ethylhexyl) Orthophosphoric Acid for the Separation of the Elements Lanthanum-Gadolinium by Reverse Phase Partition Chromatography, 84
Pigeon : Centrifugal Fibres to the Retina in the (W M. Cowan and T. P. S. Powell), 487
'Piggy-back' Phagocytosis (Dr. A J Sbarra, Dr W. Shirley and W. A. Bardawil), 255
Pigment of the Hermaphrodite Gland of *Arion ater rufus* L. (O. Lùsis), 1191
Pillai, S. · Celloidin Impression Technique for Recording Egg Sculpturing in *Aedes* Mosquitoes, 212
Pinched Lightning (B. T Matthias and S. J. Buchsbaum), 327
Pinus sylvestris L. Morphological Influence of Exudates of Mycorrhizal and Non-Mycorrhizal Fungi on Excised Root Cultures of (P D. Turner), 551
Pitsch, Bonnie L., and Prof. Mitsuru Nakamura : Role of Thiamine and Amino-acids in the Nutrition of *Shigella sonnei*, 359
Pitt, Frances Bird Study, *review*, 1007
Pituitary Extract : Œstrous and Ovarian Response of the Ewe to a Horse Anterior (N W. Moore and J. N. Shelton), 1283
Pituitary Gland in Ketogenesis : Role of the (Dr. P. A Mayes), 939
Piveteau, Jean (edited by)· Traité de Paléontologie, Vol VI, *review* by R. J. G Savage, 64
Placenta as a Homotransplant (J. W. Uhr and S. G. Anderson), 1292
Placentæ in the Raccoon Two Morphological Types of (R F S Creed and J D. Biggers), 103
Planets and Satellites (edited by Gerard P. Kuiper and Barbara M. Middlehurst), Vol 3, *review* by R. O Redman, 48
Planets . Chondrules and the origin of the Terrestrial (Dr. J. A. Wood), 127
Planning, Vol 28, No. 459 (February 19, 1962), Problems of Export Marketing, 536
Plant Analysis by X-ray Fluorescence Spectrography · Determination of Calcium and Potassium (D F Ball and Dr D F. Perkins), 1163
Plant Cells with Concomitant Inhibition of Ammonium Uptake · A Specific Stimulatory Action of Indolyl-3-Acetic Acid on Potassium Uptake by (I. Ilan), 203
Plant Community (Prof. Herbert C. Hanson and Ethan D. Churchill), *review* by L. M. J. Kramer, 1004
Plant Ecology : Introduction to (Dr. Maurice Ashby), *review* by L. M J Kramer, 1004
Plant Leaves . Secretion from Pores of Surface Wax on (D M. Hall and L. A. Donaldson), 1196
Plant Phenolics and their Industrial Significance, symposium on, 1024
Plant Phenolics Group of North America, meeting, 1024
Plant Tissue for Electron Microscopy Embedding Large Slices of (B. E. Juniper), 1296
Plant Virus Use of Formalin-treated Antigen in the Production of Antiserum to a (M. Hollings and O M Stone), 607
Plantin, L.-O., *et al.* · Acute Radiation Injury , Pathophysiological aspects of the Massive Leakage of Albumin into the Gastrointestinal Tract, 1243
Plants Effects of Indolyl-3-Acetic Acid on the Movement of Nutrients within (C. R. Davies *et al*), 204
Plants · Evidence for an Alternative Pathway in the Bean, Role of the Shikimic Acid Pathway in the Formation of Tryptophan in Higher (L H. Weinstein *et al*), 205
Plants : 2-Hydroxyphenylacetic Acid, a New Constituent of Higher (H Kindl and G. Billek), 579
Plants Interference by Tungsten with Uptake of Molybdenum by (H. J. M. Bowen and P. A. Cawse), 399
Plants Metabolic regulations of the Alkaline effect of (Dr. W Dijkshoorn), 165
Plants : Toxic Effect of Urea on (I J. Cooke), 1262
Plasma Clearance of *p*-Aminohippuric Acid by the Kidneys of Fœtal, Neonatal and Adult Sheep (D Pauline Alexander and D A. Nixon), 483
Plasma Dynamics · Symposium of (edited by F. H. Clauser), *review* by P. F. Little, 73
Plasma Electron Temperature and Density from Thomson Scattering of an Optical Maser Beam . A New Method for the Determination of (T. P. Hughes), 268
Plasma Fibrinolytic Activity in the Immature Animal (B G R. Neville and R. G. Spector), 1284
Plasma · Ion Waves in a Bounded (P F. Little), 1137
Plasma Kinin Formation · Anti-Heparin Agents as Inhibitors of (Desirée A. J. Armstrong and J. W. Stewart), 689
Plastics Industry Education Fund (grants), 1024

MICRODOL-X

AN IMPORTANT NEW DEVELOPER FROM KODAK

The new Kodak 'Microdol-X' Developer is an excellent fine-grain negative developer offering the following advantages:—

- Clean, fog-free negatives
- Low graininess
- Maximum sharpness of image detail
- Minimum loss in effective film speed
- Little tendency to sludge with use, or in hard water
- No formation of scum on exhaustion, aeration or replenishment
- Even better definition at a dilution of 1 + 3
- An average development time in undiluted 'Microdol-X' of only 10 minutes at 68°F or 7 minutes at 75°F (roll and miniature films)

Kodak 'Microdol-X' Developer is available in packings up to and including the 1-gallon size in single-powder form. The larger sizes of developer are in two-powder form. The replenisher for 'Microdol-X' is available in two-powder form.

Write for details:—

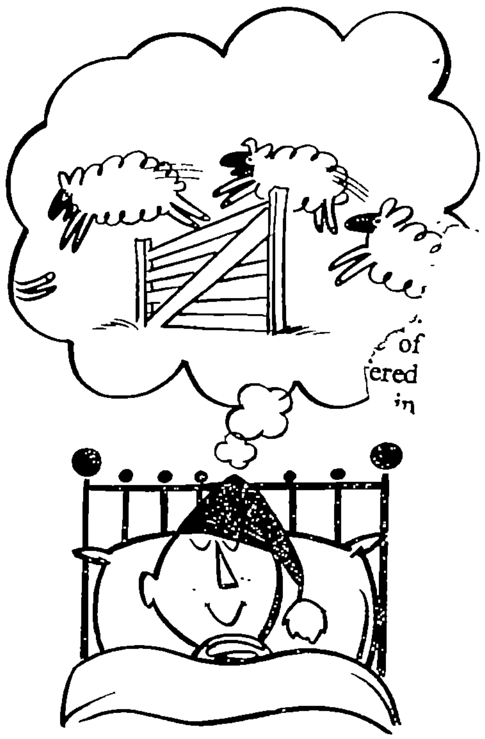
It's easier with a
COULTER COUNTER

Counting and sizing with Coulter is anything but a tiring business and you can sleep peacefully in the knowledge that you have the most advanced equipment for this exacting work.

The Coulter Counter is based on the simplest possible principle and manufactured to the highest standards. The result is an exceptionally accurate instrument with a high degree of calibration stability. It will count and size at least twenty times as fast as any other method . . . without any operator fatigue and without any calculations more complicated than simple arithmetic.

- **Counts up to 5,000 particles per second**
- **Sizes from .25 microns upwards**
- **Wide size range (1:64000 Volume ratio)**
- **Complete size distribution analyses made in under 1 hour**
- **On-Stream quality control possible**



full details will be sent on request

FUTURE OF BRITISH OVERSEAS RESEARCH AND SCIENTIFIC AID

IN her concluding B.B.C. Reith Lecture, Dr. Margery Perham urged the importance of Britain striving to keep, and indeed to increase, her great knowledge of the peoples of her former empire and the measure of goodwill and understanding which exists between them. To that end, Britain's greatest contribution would be to put all her strength and experience behind the international organs in which alone lie the possibility of peace, order and mutual help. The aid Britain gives must not even bear the moral taint of philanthropy and much will depend on Britain's dealings here with many thousands of African students and, on the other side, on the readiness of our young doctors, lawyers, scientists, and, above all, teachers of every kind, to go out for at least two or three years to serve the great needs of Africa, and to serve in the spirit which Africa now demands. This, in turn, requires that those who hold authority in Britain should facilitate such ventures, perhaps by secondment, and make them a qualification and not a handicap in a career.

Dr. Perham does not overlook the value of the uncounted and rewarding contacts between individuals and groups from each side which have been possible under the official relations or of the service which some 20,000 missionaries from all the churches are quietly rendering in Africa. She recognizes, however, the full force of the new nationalism which may dictate policies from the blood and not from the brain and that it is possible that the lamps of Africa may go out even before they are fully alight, as some of the lamps of Europe have gone out. Whether they do or not will depend very much on the degree of understanding and help which people in the West give to Africa during the next two or three critical years.

In these Reith Lectures, Dr. Perham very fairly assesses both the British achievements in Africa and the rise of African nationalism, particularly the factors which encouraged the development of anti-colonialism. She notes how our tardiness in training Africans for the higher posts in the Civil Service presented serious problems in the transfer of power which remain as grave weaknesses in the new States, so that the African States are strained as on a rack between their political ends and the lack of nearly all the means to achieve them. Unostentatious help and friendship, she reminds us again, might just turn the trembling scale in these States in favour of reason and justice, if not of democracy as we define it, for Britain was their political nurse and tutor, and we bear some responsibility not only for their public virtues but perhaps even more for their political defects. We should therefore show understanding and restraint to the eleventh hour.

Dr. Perham pays a generous and deserved tribute to the men of the Colonial Service and especially to those who served as district commissioners, and while she considers it is a fair count against us that, even after recognizing the growing demands for self-government, we did little to prepare for it, she admits that she herself, like many others involved in Colonial affairs between the Wars, was taken by surprise at the speed with which African nationalism advanced. As late as 1939 the opinion was expressed that in Africa, at any rate, we had unlimited time in which to work, and that attitude may be one factor responsible for the gradualism which in Central Africa has been overtaken by impatient nationalism before generous proposals for educational and other welfare services, including a new multi-racial university, could close the gap between the races and develop a multi-racial community.

It is against this background, and against the vision and urgency which characterize recent reports from the Rockefeller Foundation and the Carnegie Institution of Washington, that the critical importance of the Department of Technical Co-operation is to be seen and the belated report on *Colonial Research** makes such disappointing and even disturbing reading. Beyond a brief reference to the need to ensure continuity of assistance from the United Kingdom to countries evolving from colonial to independent status and to the creation of the Department of Technical Co-operation, to which the functions previously performed by the Colonial Office Research Department and its advisory committees and council have been transferred, there is no reference to the larger issues which give colonial research its significant place in technical assistance and in the development of the emergent territories. Apart from a note in the report of the Colonial Social Science Research Council that a resolution, suggesting that this Council should be reconstituted as an advisory body on matters relating to social science in terms which would enable it to advise on measures required to provide facilities for United Kingdom research in this field which have become independent and to provide liaison between the United Kingdom and independent territories, has been sent to the Overseas Research Council there appears to be no reference to the latter body in this report. The bland announcement that the present volume, which comes from the Colonial Secretary, will be the last to be published, is unaccompanied by any indication whether or not it will be succeeded by any other volume from the Colonial Office or the Department of Technical Co-operation.

---

* Colonial Research 1960–61 Reports of the Committee for Colonial Agricultural, Animal Health and Forestry Research; Colonial Economic Research Committee; Colonial Fisheries Advisory Committee, Colonial Medical Research Committee/Tropical Medicine Research Board; Colonial Pesticides Research Committee; Colonial Social Science Research Council; Tsetse Fly and Trypanosomiasis Committee; Director, Anti-Locust Research Centre; and Research Matters not covered by the above Reports of the Specialist Advisory Bodies. Pp. 353. (Cmnd. 1584.) (London: H.M.S.O., 1961.) 18s. net.

This is not good enough. No respect for departmental independence or unwillingness to commit another department can excuse such trifling with issues of this importance. The 350 pages of this report display a record of scientific work of the utmost importance to the dependent and independent territories alike—a record of which the Overseas Research Service and all its collaborators have every right to be proud. It is unthinkable that this work is to be curtailed or suspended. In scale, as the present report itself shows, it is too small and the need is for expansion—a task demanding vision and sound judgment as well as more generous financial support from Britain.

There is a further point here to be noted. Brief as is all the reference possible to any particular piece of research, however significant and far-reaching in its importance, in a report which covers so many fields of work and territories, even such reference can mean much to the isolated research worker in the overseas territories. Both Prof. P. M. S. Blackett and Sir Alexander Carr-Saunders have stressed the bearing of this factor on the recruitment of research workers for overseas service. To suspend the publication of *Colonial Research* without replacement by some equivalent and more effective publication would be a disservice to research that might well involve expenditure many times the trifling saving apparently achieved. Such parsimony is inconceivable except in the light of the Government's own record of lack of imagination and penury in this field.

If, in fact, the United Kingdom is to continue to support research in the dependent territories and to assist the dependent territories in this field, Parliament and the taxpayer are entitled to a full account of the way in which public money is expended. From this point of view, as has been emphasized from time to time in these columns, *Colonial Research* has not been entirely satisfactory. A series of reports from specialist bodies, however adequate and admirable in themselves, is ill-adapted to interpret to Parliament or the general public exactly what is the significance of the work in a wide range of fields. Some general account, picking out, if necessarily merely by way of illustration, some features of the year's work or outstanding advances, would have conveyed far more effectively the value of the research in progress and perhaps enlisted the public understanding and support that are essential if overseas research is to be prosecuted on the scale its importance demands.

This the Colonial Research Council never attempted to provide, and it was hoped that when the Overseas Research Council was constituted the latter would make good some of the defects and omissions of its predecessor. So far, something like a conspiracy of silence appears to surround the Overseas Research Council. No report has yet come from it, and the last two reports on *Colonial Research* seem to be at pains to avoid mentioning it, as is the Minister for Science whenever he discusses the organization of research in Britain. It is understood that, unlike all the other Research Councils, the Overseas Research Council has no funds of its own, and that it now comes under the new Department of Technical Co-operation.

This position is anomalous and in itself indicates a lack of imagination and of judgment that are disturbing. If the opportunities in overseas research are to be seized and the full contributions which Britain could make in this way to the development and welfare of the dependent and emergent territories are to be realized, the Overseas Research Council should be provided with its own appropriate funds and placed alongside the other Research Councils in its proper place—under the Minister for Science. Its demands on Britain's scientific and technological resources are to be assessed in the first place with those of the other Research Councils, and to suggest that the Department of Technical Co-operation would be unable, if this were done, to take care of the demands for other kinds of technical assistance is an unjust reflexion on the ability of the Minister, if not an outright insult to him. The problems of organization are indeed difficult ; but such problems are solved by facing, not running away from, them.

The time is long overdue for a clear explanation of what the Overseas Research Council is doing and what it is intended to do, and of how exactly it fits into the Government's plans for assisting the dependent and the independent territories. There is no reason to doubt the determination with which Mr. Denis Vosper is tackling his vital and responsible task, but there is every reason to believe that he will need the understanding and resolute support of all those, whether scientists or technologists or not, who appreciate the significance of technical assistance in general and research in particular in the world to-day, if he is to secure the resources he needs to discharge his responsibilities and the power to use those resources most effectively. The Overseas Research Council should be one of his most important instruments and a clear statement on its position, its functions and resources would provide a focus for constructive criticism and firm support. Its absence now can only indict the Government's sincerity in the whole field of technical co-operation and overseas aid.

Even now such suspicions are not entirely unjustified. *Colonial Research* provides more than an impressive record of scientific achievement with which Britain may well be proud to be associated. It includes also, in its lists of committees, sub-committees and councils responsible for guiding that work, names of scientists not only distinguished for their own scientific standing and achievements but marked also by the vision and imagination which they have brought to bear on matters of public policy with which science is concerned. Nevertheless, from all the bodies responsible for research overseas has come no report or statement comparable in insight and imagination with, for example, the most recent surveys of the President of the Rockefeller Foundation or of the President of the Carnegie Institution of Washington. Furthermore, the Minister for Science and members of his Advisory

Council on Scientific Policy have repeatedly shown a capacity for exposition and interpretation, for awareness of human issues, in no way inferior to those shown by Dr. Caryl Haskins and Mr. J. C. Harrar. Why is it, where matters of overseas research and technical assistance are concerned, the leadership to which Britain's past efforts and record fully entitle her is allowed to pass tamely into other hands ?

To ask this, or to suggest that the scale of our contribution to technical assistance in general and to overseas research in particular needs to be increased, is not to ignore or disparage what has already been done. Under the Colombo Plan alone the United Kingdom contributed in 1960–61 £35·9 million in capital and technical assistance, making a total of £182·78 million (of which £175·72 million is capital aid); in the current financial year some £180 million was provided in aid to underdeveloped countries, of which about £160 million is for Commonwealth countries, but the significant factor, as the latest report of the Consultative Committee shows, is the urgent need for more rapid development and for more determined efforts to keep pace with the unprecedented growth of population. What is true of South and South-East Asia is no less true of Africa and the West Indies and other areas, and it is what is done in the years immediately ahead that may well be decisive.

It is not belittling what has already been done to urge that more is needed and that because our resources are limited they must even more imperatively be used wisely, imaginatively and boldly. In Government circles it is this that appears to be lacking. We would seem to have established the appropriate instruments but to be unable or unwilling to use them fully or effectively, and it is the great merit of Dr. Perham's Reith Lectures that they reveal something of the measure of that opportunity, as indeed did Mr. John Strachey in his *The End of Empire*, as *Colonial Research* conspicuously fails to do.

Even from our own selfish interest, it is essential that the nation should realize and grasp the new type of opportunities that are ours to-day both at home and abroad. In them we can, as Mr. Strachey truly writes, best show our creative powers and write an enduring name on the roll of history. It is the things of the mind and the spirit that make or mar national fortunes and it will be by serving the peoples of the world that Britain can be great. To serve them by a sustained effort to provide them with both the material means and the technical skills which they desperately need may indeed be the highest and most aspiring ideal we can set ourselves, and it is not in conflict with the continued improvement and perfecting of our own society: rather it is a contribution to that end.

The scientist and technologist will accordingly salute the passing of *Colonial Research* with deep appreciation of the contributions to scientific advance and to human welfare and development made in so many varied fields by the patient and devoted work of many investigators, often working in isolation and deserving of more generous support and professional recognition. That appreciation will be accompanied by regret that those on whom the ultimate responsibility for directing and supporting that work have so seldom seemed aware of its importance or implications, so lacking in any sense of urgency, or consciousness of the opportunities for leadership. Appreciation and regret, however, may fittingly be accompanied by the hope that, under some such title as *Overseas Research*, a succeeding series of volumes will do something more than continue a record of noteworthy achievement in many branches of science of which Britain may continue to be proud. It is to be hoped that the new volumes will display also imaginative insight into the issues and opportunities with which overseas research and technical assistance in general confront us, readiness to make the necessary sacrifices and a determination to offer the service and leadership that are demanded. It is not indeed that the financial contribution needed is likely to be excessive; wise planning, careful timing and a proper sense of proportion and choice of objectives are likely to be the vital factors; but once the projects are selected, adequate support and encouragement and freedom from 'start and stop' practices are essential.

Far more significant is likely to be the demand made on our own limited resources of scientific and technical manpower, and that is why, when full account is taken of the shortcomings of Government policy which are so apparent from *Colonial Research*, it is imperative that neither overseas research nor technical assistance should be regarded as matters for Government alone. Mr. Denis Vosper and Lord Hailsham are entitled to all possible assistance from the universities and colleges of technology and from many professional institutions along lines such as Prof. P. M. S. Blackett, for example, has indicated. It is because of its potentialities in organizing such support that the Overseas Research Council is so important and that it should be given a fitting place alongside the other Research Councils in displaying the nation's scientific and technical resources.

There may well be some difficult administrative problems, but not such as to defeat realistic co-operation between the Minister for Science and the Secretary for Technical Co-operation, and it should be an advantage that the Department of Technical Co-operation has an opportunity to make a fresh start. Given real determination on the part of the Government and a sense both of urgency and the decisive importance of leadership the new Department should be at no disadvantage. There must, however, be no more parsimony and none of the fumbling and shortsightedness that has allowed the Peace Corps of the United States to overshadow so completely the Voluntary Service Overseas launched even earlier by Britain, and leadership in technical assistance to pass from our own research institutions to the great foundations of the United States. The final volume of *Colonial Research* is, above all, a challenge, and the future of Britain itself may well depend in large measure on the vision, the courage and the determination with which that challenge is accepted and faithfully translated into terms of service for the overseas peoples.

GALILEO'S ACHIEVEMENTS

ASKED to name Galileo's greatest scientific achievements, most people would probably point to his discoveries in astronomy and dynamics. The originality of his telescopic observations, their great importance, their revolutionary effect on man's outlook on the universe, are all undoubted. But how great was his achievements in dynamics ? Not nearly so great, at first sight, as has commonly been supposed. Newton, for example, in a celebrated passage in the *Principia*, seems to imply that Galileo was familiar with both the first and second laws of motion. But Galileo, even if he were fully aware of the importance of inertial motion, which is doubtful, only recognized such motion as a 'terrestrial' phenomenon, rectilinear to a first approximation, but in reality circular along the Earth's surface. As for the second law of motion, there is nothing beyond the merest hint of it in any of Galileo's writings. In fact, his two great achievements in dynamics, the derivations of the law of falling bodies and of the parabolic path of a projectile, were largely kinematical rather than dynamical, at least as treated by him. Both these achievements were undoubtedly of great importance. For example, *Lemma X* of Newton's *Principia*, later used in his solution to the problem of Kepler motion, is a direct generalization of Galileo's law of falling bodies. Moreover, the derivation of the parabolic path of a projectile was memorable not only historically, as the first important prediction of modern science, but also for the notion of compounding independent motions on which it was based.

Apart from these two specific achievements, Galileo made another, and perhaps equally important, contribution to dynamics. If one considers his finished work on the subject in the *Discourses on Two New Sciences*, then one is struck by its essentially modern spirit compared with that of his predecessors, or contemporaries, or even some of his successors, such as Wallis in his *De Motu*. Here we have something recognizably in the *genre* of mathematical physics as we know it to-day. In this respect Galileo had only one predecessor, Archimedes, to whom he was undoubtedly indebted for certain aspects of his approach to physics. But Archimedes (and this is one of the most curious and puzzling facts in the history of science) never seems to have given much attention to the problem of motion. Galileo's work in dynamics, such as it was, with all its inevitable limitations, was thus the first modern *De Motu*. This was revolutionary at the time, and still seems recognizably modern to-day, just because it retained so little of Aristotle's influence. It was at this point, in freeing himself*, and dynamics, from a great part of Aristotle's influence, that Galileo made what was probably his greatest contribution both to science and dynamics. He never attained to the true, universal concept of inertial motion, or to any sort of understanding of circular motion: the honour of so doing was reserved for Descartes. But there was no future for the detailed, quantitative development of dynamics on the lines of Descartes' *Principia*, whereas Galileo's work served as the model for Newton's final synthesis of the subject.

It is this which makes Galileo's early, unpublished work *On Motion* of such absorbing interest. For in it we see him in the very act of freeing himself* from two of the most unfortunate Aristotelian presuppositions, the belief in light bodies, and in the impossibility of a vacuum. In the *On Motion* Galileo conclusively explodes the notion of light bodies. All bodies are intrinsically heavy, and tend to move towards the centre of things. The fact that they sometimes do not, but move upward, is contingent only, having a simple hydrostatic explanation in terms of the surrounding medium. Equally conclusive are Galileo's arguments against Aristotle, and in favour of the possibility of a vacuum and motion therein. It is only *in vacuo* that the proper natural motion of heavy bodies can be studied. For example, that of a perfectly smooth sphere on an equally smooth inclined plane.

It is perhaps difficult for anyone unfamiliar with the period to realize the magnitude of Galileo's achievement in freeing himself from these and other peculiar features of Aristotle's physics. The difficulty is rather to understand how any intelligent person, let alone Galileo, could ever seriously have entertained such bizarre notions. But when we recall that Descartes, whose specific contributions to dynamics were equally great, if not greater, than Galileo's, never freed himself from a belief in light bodies, or in a *plenum*, whereas Galileo, unlike Descartes, never escaped from the tyranny of the Platonic or Aristotelian circle, then we begin to realize how plausible and all-pervasive the Aristotelian *weltanschauung* was, and how difficult it was to escape from its influence.

I have mentioned the part played by hydrostatics in Galileo's break with the false, Aristotelian notion of light bodies. His mastery of this subject is evident from the *Discourse on Bodies in Water*. This work was occasioned by a controversy between Galileo and his Aristotelian opponents. The axioms, definitions and theorems at the beginning of the treatise form the necessary propadeutic to Galileo's devastating reply to the criticisms levelled against Archimedes by these opponents, especially Buonamico. First, he disposes of the seeming paradox of the floating of a hollow denser-than-water body; then he refutes Aristotle's doctrine of natural levity as opposed to the belief of Plato and the ancients that levity was due to the action of the surrounding medium. This leaves him with the puzzling question of the floating of thin plates of denser-than-water materials.

Galileo's treatment and discussion of this problem takes up the remainder of the treatise and was for me the most interesting and revealing feature of the whole work. In it we see displayed, one by one, those qualities which together made him, with the possible exception of Kepler, the first true follower of Archimedes, the first mathematical-physicist of modern times. First the unrivalled observer: who before Galileo (and the phenomenon went back at least to Democritus) had looked closely enough to see that the plate actually lay *beneath* the surface of the water ? Next, the capacity to apply a known principle (Archimedes') to a new situation: the true system under consideration was not the plate alone, but the plate together with the little pocket of air above it. It was the upthrust of the water on this

---

* Not, however, entirely by his own unaided efforts. Galileo's debt at this point to his master, Benedetti, was very great.

whole volume which balanced the weight of the plate. Lastly, the mathematician able to derive an exact, quantitative, general result applicable to all such situations: to discover, in Salusbury's fine rendering into Jacobean English, "what proportion several Figures of different Matters ought to have, unto the Gravity of the Water, that so they may be able by vertue of the Contiguous Air to stay afloat". To this problem Galileo gives the complete answer in *Theorem VI*, in which he brings out the importance of the maximum possible height of the little 'rampart' of water surrounding the plate.

From this general result he then derives a number of characteristically provocative theorems calculated to confound his adversaries, such as: "All Matters, how heavy soever, even to Gold it self, the heaviest of all Bodies, known to us, may float upon the Water" (*Theorem VII*). The treatise ends with an interesting discussion of the views of Aristotle and Democritus on the same problem.

These two works[1,2], the early one on *On Motion*, and the *Discourse on Bodies in Water*, reveal many of the varied talents which went to make up Galileo's scientific genius. The remaining work, *On Mechanics*, also reminds us of that mechanical bent of mind which he shared with Archimedes and Newton, and which expressed itself in the construction of the telescope and other scientific apparatus. Apart from the section on percussion, a subject in which Galileo made no progress, this work is devoted to a study of the simple machines, and contains nothing original. It is chiefly remarkable for Galileo's consistent use of the principle of virtual velocities. Galileo could scarcely be called the 'originator' of this principle, but his confident manner of using it was novel and very influential.

These three works of Galileo are, finally, important not only as valuable source material in the history of science but for their reminder of the many-sidedness of his interests and abilities. This many-sidedness was something he shared, of course, with Kepler, Descartes and Newton. But although their common breadth of interest could be regarded as a natural outcome of the cultural background of the day, this is not to say that it was an unimportant factor in the birth of dynamics to which each brought his own peculiar gift. For example, in each the philosophical caste of mind seems to have been of crucial importance. Without Kepler's interest and passionate belief in neoplatonic symbolism and world harmony it is hard to believe he would ever have discovered his laws of planetary motion. Galileo, without his complete mastery of Aristotelian philosophy, would never have overthrown Aristotle. If Descartes had been only a pure mathematician and not also a philosopher he might never have been able to formulate the true principle of inertia, or free himself from the tyranny of the platonic circle, any more than Newton would have been able to extract the pure gold from Descartes' *Principia* while demolishing the philosophical system in which it was embedded and replacing it by a better one of his own. One is thus led to speculate: if dynamics sprang from the wonderfully rich intellectual, philosophical and religious background of the Renaissance, it is possible that its most vigorous descendant, fundamental particle physics, will ultimately languish in the over-scientific atmosphere of the twenty-first century? That this should happen is perhaps the secret hope of an increasing number of scientists who have always subscribed to the idea of science as the servant rather than the master, or even destroyer, of life, but who now begin passionately to desire that this should be so, and wonder how it can ever be brought about. A long period of relative stagnation in fundamental scientific advance would certainly give civilization the opportunity of absorbing and integrating to herself the tremendous scientific advances of the past half-century, just as the Middle Ages had time to absorb and synthesize the equally disturbing new *corpus* of Greek science. If this should happen, then one can confidently expect that a new Galileo would ultimately arise, equally master of the total civilization of his day, and equally capable of demolishing its current, over-complicated *De Motu*, and preparing the way for a new dynamics perhaps as obvious, in retrospect, as the dynamics of the seventeenth century to those who understood Newton. For as Galileo himself remarked [Drabkin's translation of *De Motu*, p. 38], "truth hath the property that it is not so deeply concealed as many have thought; indeed, its traces shine brightly in various places and there are many paths by which it is approached. Yet it often happens that we do not see what is quite near at hand and clear".

All those interested in seventeenth century science will be indebted to I. E. Drabkin for his lively and readable translation into English of Galileo's *De Motu*, and for his introduction to that work. Likewise to Stillman Drake for his introduction to the *Le Meccaniche*, and especially for that to the *Discourse on Bodies in Water* in which the setting of the work, its motivation, and its great importance for the remainder of Galileo's scientific career are all clearly displayed. Needless to say, both books maintain the high standards of scholarship and production so long a feature of American publications in the history of science. J. W. HERIVEL

RESTLESS ATOMS IN SOLIDS*

By DAME KATHLEEN LONSDALE, F.R.S.

THE most striking characteristic of a solid is rigidity which, however, is not simply a property of symmetry and periodicity of atomic arrangement, since the atomic arrangement in a glass is not a regular one. Rigidity is dependent rather on the fact that although atoms in every state of matter are moving, yet at sufficiently low temperatures the movements are not, in general, violent enough to cause the relative atomic positions to change. If, however, a crystalline solid contains imperfections, interstitial atoms, vacant sites, dislocations, impurities or grain boundaries, these may well move quite large distances even though local atomic movements are small: and although the mean atomic vibrational displacements are seldom more than 0·1–0·3 Å. at room temperatures, yet occasional movements are much larger, and single atoms sometimes travel large distances in a solid. Different kinds of atoms or ions in a compound will vibrate with different mean amplitudes, and molecules undergo translational vibration, libration and some distortion. All these movements produce or affect so many physical and chemical phenomena that it is not possible to mention more than a selection.

---

* Substance of a Friday Evening Discourse delivered at the Royal Institution on December 8, 1961.

Melting, softening and crystal transformations. Theory and experiment both show that atoms are not at rest even at 0° K. They have zero-point energy. As the temperature is raised they also have thermal energy, and this increases until the atomic vibrations are so large that the forces between the atoms can no longer keep the solid rigid in that particular arrangement. If the solid is amorphous it will soften and become a viscous liquid; but if it is crystalline then it takes up latent heat and melts, or it changes its crystal form. One of the more spectacular of such changes is the diamond $\rightleftarrows$ graphite transformation. Diamond begins to change to graphite when heated, in the absence of oxygen, to upwards of 1,500° C. Even at this temperature, however, theory indicates that the vibration displacements of the carbon atoms in diamond have a mean value of less than 0·15 Å.

At room temperatures the Na^+ ions in sodium chloride have a mean vibration displacement of about one-twelfth of the Na^+—Cl^- distance; that of the Cl^- is a little less. But melting takes place when the ratio is about 1 : 6 (ref. 1).

Thermal conduction and thermal expansion. A simple experiment shows that if a copper rod is heated at one end, the increased atomic amplitudes are very quickly transmitted along the rod and the rod simultaneously expands. These two properties do not necessarily go together, however, for diamond conducts heat quite as well as aluminium, but it has a very small expansion coefficient at room temperatures. The expansion of organic crystals such as naphthalene or anthracene is not only anisotropic but many times (up to about × 200) larger than that of diamond.

For purposes of calculation of diffraction effects thermal vibrations in simple crystalline structures may be regarded in either of two ways: (1) as a superposition of a very large number of stationary patterns, in which the atoms are displaced from their mean, regular positions; (2) as a superposition of stationary simple harmonic waves. This only applies, however, when the substance is in a state of thermal equilibrium. If it is expanding then the vibrations must be anharmonic.

Volatility, solubility. At the surface of a crystal the molecules may be subjected to an unbalanced force. If so they will tend to fly off. This may be useful, as when the substance *para*dichlorbenzene, for example, is used to preserve blankets from moths. The molecules fly off the surface so fast that in a few hours exposed crystals will have disappeared completely. But in an X-ray tube, or in an electric light bulb, the emission of atoms from a hot tungsten filament is a real nuisance. In the case of an X-ray tube it contaminates and reduces the characteristic radiation emitted and also increases the absorption of the window by covering it with a tungsten film.

The function of thermal vibration in the process of solution of a solid in a liquid is not so obvious. Atoms or molecules are removed from the surface of the solid and mingle with those of the solvent. In the case of Na^+Cl^- dissolving in water it is not difficult to see that a vibrating ion at the crystal boundary may easily form a temporary attachment to the polar water molecules, strong enough to detach it from the mother crystal. A somewhat similar process may function when anthracene, say, dissolves in an organic solvent; it is while thermal vibration has temporarily weakened its attachment to the main body of the crystal that a temporary attachment to a solvent molecule can suffice to remove it. Such an attachment could well occur most easily at the 9,10-carbon atoms which are the most reactive and also[2] the most mobile.

This would explain why it is that dianthracene, which has a crystal structure very similar to that of anthracene, is nevertheless insoluble in all light organic solvents. The molecules are twice as heavy; and their 9,10-carbon atoms are no longer 'free' to form temporary attachments.

Movements at grain boundaries. The atomic vibrations at grain boundaries or in the neighbourhood of vacant sites will be larger than in the body of the crystal and therefore atoms will tend to make permanent movements of position more easily at these places. Impurities move to vacancies or grain boundaries and, if larger than the atoms of the matrix, they tend to get trapped there. Atoms tend to move across grain boundaries from a grain that is under strain to one that is not. This explains how it is that ice crystals at the bottom of a glacier are found to be very large relative to those at the top. The weight of snow or ice above imposes a strain on the ice crystals which form the glacier. Those in which this strain can be relieved by gliding grow (by transference of molecules across boundaries) at the expense of those less favourably oriented. The large crystals at the foot of the glacier are, therefore, so orientated that the basal (0001) layers, which define the directions of easy glide, lie along the direction of flow of the glacier[3].

Annealing of radiation damage. Heat treatment will heal radiation damage in diamond; and it is probable that self-annealing is going on, during neutron irradiation, simultaneously with the damage imposed. Laue photographs of diamonds which have had their density reduced by 4 per cent as the result of irradiation by fast neutrons show diffraction effects which are entirely similar to those produced by thermal vibration, except that they correspond to very much larger atomic displacements and that they are not temperature-sensitive. The random-rotation photographs of such irradiated diamonds show that all the unit cells are enlarged; it is not a case of a partly undistorted diamond containing regions of intense damage. There is no trace of diffraction spots at normal diamond spacings, and the spots due to the enlarged structure are sharp enough to show copper $K\alpha_1\alpha_2$ separation (Milledge, H. J., unpublished).

Nature of disorder in crystals. Any form of disorder which is completely random must give a diffraction effect similar to that of a gas; or if there are regions in the crystal where the disorder is essentially close-packed but amorphous, then its diffraction effect will be that of a liquid. Such effects are observed. But when diffraction effects are found which are not temperature-sensitive but which nevertheless show some symmetry and periodicity (related to that of the crystal) then the disorder cannot be random. It must affect every unit cell, or a definite proportion

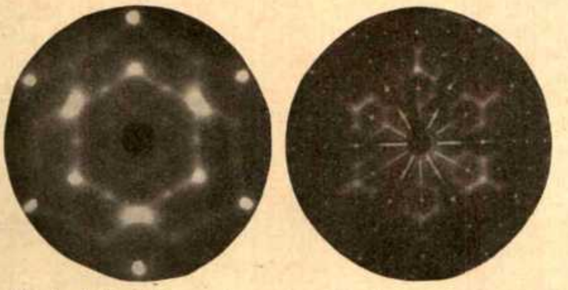

Fig. 1. Left, diffuse background on benzil photograph due to thermal vibration; temperature-dependent; right, diffuse background on trimethylsulphonylmethane photograph (Abrahams and Speakman) due to ordered disorder; temperature-independent

of the unit cells, in a partially ordered way. Such disorder may simulate thermal-vibration and cause an apparent increase of the Debye coefficients, but it will also cause a real variation of the thermal vibration, as compared with that in an ideal crystal, just as holes, impurities and other imperfections must do (Fig. 1).

Solid-state diffusion. Ionic conductivity. Gold placed in close contact with lead diffuses into it very easily. Near to the melting-point of lead, the diffusion may be as fast as that of salt through water at room temperatures. Such diffusion can occur partly because gold atoms are smaller than those of lead, partly because of the holes and dislocations in the lead structure and partly because of the large thermal vibration in the lead crystal, which allows rapid movement of vacant sites towards the common boundary where gold atoms are then trapped.

Sodium ions can easily migrate through glass. If an evacuated glass bulb is immersed in molten sodium nitrate and the evacuated space in the bulb is made conducting by emission of electrons from the hot tungsten filament; and if a voltage is imposed between a copper anode in the molten sodium nitrate and the tungsten filament acting as cathode, then a current will pass. The fact that the current is conducted through the glass by means of Na^+ diffusion is proved by the deposition of a layer of sodium on the inside of the glass bulb.

Similarly, it is stated that when yellow β-Ag_2HgI_4, which is tetragonal, changes at 46° C. to red α-Ag_2HgI_4, which is cubic, the electrical conductivity is greatly increased. In the cubic form, the three $(2Ag + Hg)$ ions randomly occupy four equivalent positions. There is therefore a random arrangement of one vacant site per unit cell and current passes mainly by means of the passage of Ag^+ ions one way and of vacant sites carrying an effective negative charge the other way.

Generation of lightning by movements of electric charge through ice subject to a thermal gradient. J. Latham and B. J. Mason[4] have succeeded in explaining how it is that a sufficient quantity of charge separated by a large distance is generated, in a cumulo-nimbus thunder cloud, for a series of lightning flashes to occur. Soft hail pellets, falling at several metres per second through the cloud, will meet a fairly high concentration of small (say, 0·1 mm. diameter) supercooled water droplets. These freeze on to the surface of the hail, and afterwards, for each such droplet, about a dozen positively charged tiny ice fragments are thrown off and are carried upwards taking their positive charge with them. The negatively charged hail pellets continue to fall. Ingeniously contrived laboratory experiments have shown that this process actually occurs, and that the charge separation is such that within 20 min. about 1,000 coulombs could be generated in a volume of 50 km.[3].

The supercooled water droplets, in freezing on to the hail, give up latent heat and there is, therefore, a temperature gradient at the surface layers of the ice. The body of the hail may be, say, 10 deg. warmer than the exterior and where the ice is warmer the thermal vibrations will permit the formation of large numbers of H^+ and OH^- ions. These diffuse to the colder surface, but the velocity of migration of the proton is perhaps ten times as great as that of the hydroxyl group. The actual proton movement is, in general, by transfer only along a single OH—O bond, with the formation of temporary $(H_3O)^+$ groups. This differential diffusion results in an accumulation of positive charge at the surface and the ejection of the positively charged ice splinters.

Change of polarity of certain ferrite magnets as their temperature is changed. Ferromagnetism results from the interaction of the magnetic moments of atoms which have unbalanced spin orbitals; it is confined to crystals where there is, within certain limits, a definite ratio of interatomic distance to spin-orbital diameter. Sometimes the interaction is direct, sometimes it occurs through an intermediate anion such as O^{2-} (super-exchange), in which case both interatomic distances and metal–oxygen–metal angle may be important. Either of these may change with temperature and do, in fact, change continuously with thermal vibration, which opposes perfect lining up of the 'atomic magnets' and which, above the Curie (or Néel) point is sufficient to prevent it altogether, leaving only paramagnetism.

In the spinels, there are two (or more) different kinds of metallic ions, which distribute themselves on two kinds of sub-lattices within the oxygen ion framework. One sub-lattice (A) consists of small tetrahedrally surrounded sites; the other (B) of larger octahedrally surrounded sites. Magnetic atoms on A sites will line up with each other (AA^+ interaction) as far as thermal vibration will allow. So do those on B sites (BB^+ interaction). But there is a negative interaction between magnetic ions on A sites and those (which may be of the same or another element) on B sites (AB^- interaction). There is, in general, a resultant ferrimagnetism, that is, a preponderance of magnetic moment in one direction. Since, however, these interactions vary differently with temperature there may be a 'compensation temperature' at which the magnetic spinel becomes an antiferromagnet and then, with further change of temperature, changes its polarity.

This occurs for a number of ferrites of which $Li_{0·5}Fe_{1·25}Cr_{1·25}O_4$ is typical[5]. At room temperatures the distribution of ions is as follows: on A sites $Fe^{3+}_{0·91}$, $Li^{+}_{0·09}$; on B sites $Li^{+}_{0·41}$, $Fe^{3+}_{0·34}$, $Cr^{3+}_{1·25}$, and it is probable that there is some local ordering of the metal ions within the respective sub-lattices. The compensation temperature is 38° C. and the Curie point is 214° C. The rather large non-magnetic Li^+ ions, which also have relatively large thermal vibrations, will certainly be a disturbing factor, especially in the small A sites.

Solid-state chemical reactions. When the photo-oxide of anthracene  is heated to 160° C.

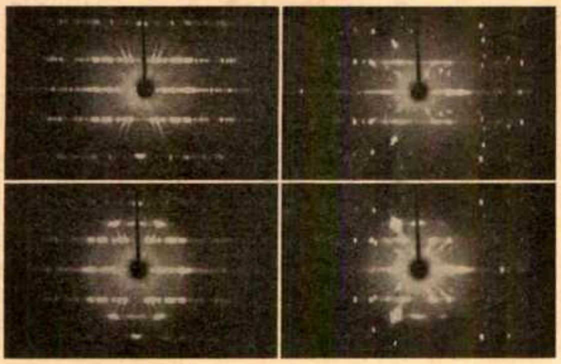

Fig. 2. Top left, initial rotation photograph of the photo-oxide of anthracene (*b* axis); top right, initial Laue photograph of the photo-oxide of anthracene, showing disorder layer lines corresponding to independent strings of molecules parallel to the *b* axis; bottom left, repetition of top left after 50 hr. X-irradiation. Layer lines due to orientated anthraquinone appearing strongly; original layer lines weaker; bottom right, repetition of top right. Laue pattern and layer lines of photo-oxide of anthracene disappearing. New Laue spots and layer lines appearing, due to anthraquinone

it explodes[6]. If a single crystal is irradiated by X-rays at room temperatures, or even at low temperatures, it changes slowly, but in the end completely, into a single crystal of anthraquinone. Laue photographs show that the photo-oxide, even when freshly crystallized, does contain some chains of molecules, parallel to the unique monoclinic axis, which are detached from their neighbours and randomly orientated about that axis. The thermal vibrations of the outer phenyl groups and of the oxygen bridge are very large and the bridge easily breaks; the hydrogen atoms are flung off and the molecules straighten out into anthraquinone, but without breaking up the structure entirely. Both structures are present in parallel at an intermediate stage (Fig. 2).

The photo-oxide of 9.10-diphenylanthracene behaves differently when heated. At 200° C. it gives off all its oxygen and reverts to the pure hydrocarbon[7]. It is evident that in this case the thermal vibrations, in breaking the bridge, cause the loss of oxygen rather than hydrogen, simply because the phenyl side-groups are too large and heavy to be thrown off and diffused out of the crystal. Diffraction experiments will be undertaken to see whether X-irradiation has a similar effect.

A POSSIBLE ORIGIN OF TEKTITES BY SOIL FUSION AT IMPACT SITES

By HENRY P. SCHWARCZ

Enrico Fermi Institute for Nuclear Studies, University of Chicago

TEKTITES are glassy objects found scattered on the Earth's surface in discrete arrays up to tens of thousands of kilometres across. They are composed of a highly siliceous and a luminous glass, devoid of crystalline phases except rare coesite[1] and nickel–iron[2] and containing particles of lechatelierite, pure silica glass.

A terrestrial versus extra-terrestrial origin for these objects has long been debated. As Viste and Anders[3] have shown, neither the presence of aluminium-26 nor any other distinctly extra-terrestrial property of tektites has yet been demonstrated. The chemical composition of tektites has been compared by various workers to various terrestrial rocks, especially sedimentary rocks, and contrasted with the compositions of meteorites and most igneous rocks. Spencer[4] has drawn analogies with impact-produced glass at known meteorite craters formed from the rocks of the impact site. Urey[5] and Barnes[6] have suggested that some impact process could produce the observed areal distribution of tektites.

I shall assume here, with Spencer[4], Urey[5] and Cohen[1], that tektites are formed on the Earth by the impact of some extra-terrestrial object. Tektites are presumably formed by the rapid fusion of rock during this impact. In this case the compositions of tektites should range widely over the possible range of terrestrial rocks, since the likelihood of (continental) impact on any given rock type should be proportional to the areal extent of the rock type. On the contrary, tektites are of restricted compositional range suggesting that the parental rock which has been fused to form them has a similar limited range of composition within which its components vary in some consistent fashion[7]. In a petrological sense they form a 'clan'.

A suitable mixture of shale and quartz sandstone[8] or an appropriate selection of igneous rocks[9] could account for the observed compositions; but it remains to be shown why just such a mixture or selection of rock types should be chosen as impact-site material to the exclusion of limestone, basalt, granite, etc.

A possible widely occurring rock type that may be the parental material of tektites is soil. It is worth while to see to what extent a soil parent rock will explain the observed properties of tektites. Soils formed within a given climatic zone on a diversity of bedrock types have remarkably similar composition[10]. The relations between the abundance of the chemical components of soil is largely a function of the weathering, dissolution and accumulation processes in the soil modified by the abundance ratios in the source bedrock. Therefore soils have a characteristic field of compositions and also form a clan, distinct from that of the parent rocks.

An average soil composition taken from analyses of temperate and humid zone soils is given in Table 1, column *A*. The data are from Glinka[11] and Bear[12].

Table 1

	A	*A′*	*B*	*C*	*D*
SiO_2	75·81	76·18	74·43	44·58	74·60
Al_2O_3	12·86	12·92	13·13	2·93	12·49
Fe_2O_3	4·18	—	—	—	—
FeO	—	3·77	4·27	14·57	4·11
MnO	0·13	0·13	0·12	0·29	0·13
TiO_2	0·93	0·94	0·83	0·13	0·90
CaO	1·83	1·83	1·76	2·28	2·04
MgO	0·88	0·89	2·01	33·76	2·01
K_2O	2·11	2·12	2·24	0·11	2·03
Na_2O	1·41	1·41	1·23	1·15	1·39
P_2O_5	0·30	0·30	nd	0·25	0·30

A, average of 11 soil analyses taken from Glinka (ref. 11) and Bear (ref. 12).

A′, same average recalculated with all Fe^{3+} reduced to Fe^{2+}.

B, average of 13 analyses of tektites taken from Barnes (ref. 25). Average includes 4 moldavites, 2 indochinites, 2 australites, 3 Ivory Coast tektites, 2 bediasites.

C, average chondrite excluding metal and sulphide (modified from average by Urey and Craig (ref. 14).

D, average soil plus 3·5 per cent chondrite. Proportion chosen to set MgO content equal to that in tektites

For comparison I have constructed an average of 13 analyses from Barnes taken in roughly equal numbers from the 4 main areal (and age) groups, Ivory Coast, Central Europe, Australia–Asia and Texas. Each of these groups presumably represents a single impact site and parent material. This average is shown in column *B*. The similarity between these two averages is striking. Although one could construct a mixture of shale and sand or igneous rock and more closely approximate a tektitic composition this comparison with soil compositions is all the more striking because such a homogeneous rock-type does exist and is accessible to metamorphism into tektites by terrestrial impact processes. However certain discrepancies are noted between these averages:

(1) As in the sedimentary rock mixtures[8] iron is present in the starting material mostly as Fe^{3+} while it is mostly as Fe^{2+} in tektites. This point has been discussed by Friedman, Thorpe and Senftle[13], who conclude that the heating process alone could account for most of the reduction. The presence of lechatelierite particles indicates that temperatures as high as 1,700° C. have been reached during formation. For the reaction:

$$Fe_2O_3 + SiO_2 = Fe_2SiO_4 + \tfrac{1}{2}O_2 \qquad (1)$$

$\Delta F = -7{\cdot}8$ kcal. at 1,527° C. and decreases at higher temperatures so that even in the absence of any reducing agent the reduction of iron is favoured. No doubt the 2–8 per cent humic matter present in most soils would also contribute to the reduction of the iron.

(2) Magnesia and equivalent FeO (column *A′*) are lower in soils than in tektites. The magnesium deficiencies are such that addition of a mixture of MgO and FeO to soil in the ratio of MgO : FeO = 1 : 0·45 would produce an average tektite composition. The ratio of these two oxides in stony meteorites is 1 : 0·43 (ref. 14). In column *C* is shown a mixture of soil and 3·5 per cent chondrite. The proportions are chosen to give the appropriate MgO content (2·01 per cent). Such a mixture could occur in Nature if the tektites were produced by impact of a stony meteorite and there occurred some mixing of the silicate phases of the meteorite with the soil of the impact site. However, no appreciable mixing of the metal or sulphide components appears to have occurred. This is also indicated by the low nickel content in tektites observed by Ehmann[15].

Taylor, Sachs and Cherry[7] observed that of all major element abundances studied in tektites only that of calcium showed no significant correlation with any other element. Presumably the source of the parent tektite material contains varying amounts of a phase containing only CaO (or $CaCO_3$). This is probably material from the almost ubiquitous zone of calcium enrichment found at various depths in temperate-zone soil profiles. The varying CaO contents would correspond to varying depths of sampling by the impact process.

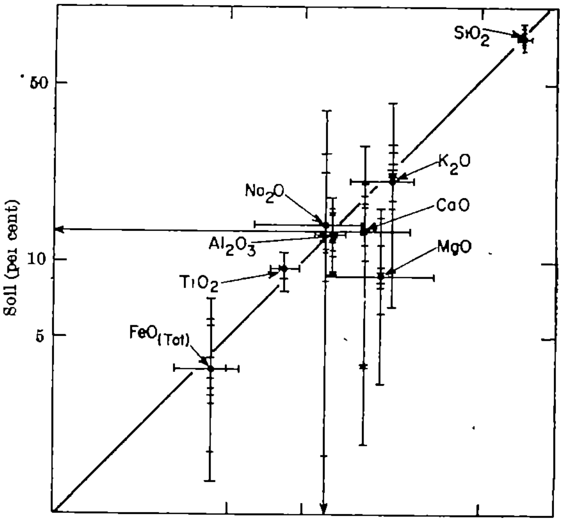

Fig. 1. Major element composition of eleven soils versus mean composition of each of four major tektite groups (moldavites, Asia–Australia, bediasites and Ivory Coast). K_2O, Na_2O, CaO, MgO and TiO_2 × 10. Logarithmic plot

The trace-element abundances of tektites have been studied by Preuss[16], and more recently some individual elements have been measured by various workers (nickel, Ehmann[15]; rubidium, strontium, Schnetzler and Pinson[17]; lead, uranium, thorium, Tilton[18]; gallium, germanium, Cohen[19]; lithium, cæsium, Taylor and Sachs[7]). Using Preuss's data for the sake of its completeness I have compared the rank of the abundance-levels for tektites and two possible source rocks, soil and shale (Fig. 2). The abundance ranking for tektites agrees for most elements with that of soils, and less closely with that of shales, which are of course of related origin. Other possible source materials, such as igneous rocks and sandstones, agree more poorly.

Gases included in bubbles within tektites have been studied by F. E. Suess[20], who found that these cavities contained carbon dioxide, carbon monoxide and water. More recently H. Suess[21] observed that the gas pressure in these cavities was very low, but that on heating crushed tektites they did evolve carbon dioxide, carbon monoxide, hydrogen and water. If the tektites were produced by fusion of soil these gases were presumably formed by the thermal decomposition of humic matter plus the adsorbed water of the soil. Note, however, that carbonaceous matter is also present in shales: an average of 44 shales compiled by Clarke[22] contained 0·8 per cent carbon.

Studies of lead, uranium and thorium in tektites by Tilton[18] showed that tektites contain modern lead such as would be derived from a typical crustal rock-system in which $^{238}U/^{204}Pb = 9{\cdot}8$ and $^{232}Th/^{204}Pb = 3{\cdot}9$. However, the observed values in tektites were 38·5 and 5·4 respectively. If the parent material of the tektites had had such high uranium and thorium contents for more than 50–100 million years a measur-

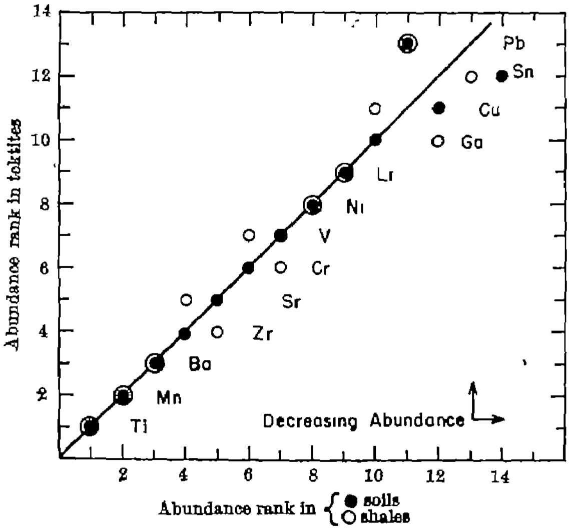

Fig. 2. Relative abundance rank of trace elements in tektites (Preuss) versus rank of same elements in shales (●) (Turekian, K. K., and Wedepohl, K. M., *G.S.A. Bull.*, 72, 175, Table 2; 1961) and soils (○) (ref. 12)

able deviation in the ^{206}Pb/^{207}Pb and ^{206}Pb/^{204}Pb ratios should have been observed. It is unlikely that thorium and uranium are enriched with respect to lead by the heating process alone. Therefore the tektites must have been derived from a rock of less than 100 m.y. age, that is, Cretaceous or Tertiary. In view of the limited surficial extent of Tertiary and Cretaceous rocks it seems an improbable coincidence that four (or more) random impacts, producing the four main families of tektites, should all have fallen on such young rocks. Soils, on the other hand, are known to be enriched in uranium and thorium, adsorbed into humic matter[23]. Such adsorbates would be short-lived since the humic matter is constantly being oxidized and carried out of the soil with a half-life of a few thousand years. The small amount of radiogenic lead produced in this interval by the decay of the adsorbed uranium is presumably carried away with the oxidized humic acid and would always be in low levels compared with the common and radiogenic lead of the mineral components of the soil.

With respect to the impact process itself, Bjork[24] has shown that on "hypervelocity" impact of a large iron meteorite the highest upward velocities are obtained by material originally located at and near the ground surface of the impact site. Material with such high velocities oriented at high enough angles to the horizon to follow intercontinental trajectories will therefore of necessity be near-surface material.

In conclusion, I have demonstrated that a possible parent rock for tektites is terrestrial soil. Soil forms a discrete, geochemically well-defined family of rock types which, with some *ad hoc* modifications, match the family of tektite compositions. Unlike the various mixtures of sedimentary or igneous rock types which have been proposed, soil is truly ubiquitous, covering all land surface except high mountains and deserts. Barnes[25] and Hawkins[26] have drawn comparisons between tektites and fulgurites. These latter would also be formed by fusion of soil, though by lightning rather than impact. I believe such a process is ruled out by the geographical distribution and the recently described occurrence of nickel–iron spherules in some tektites.

A test of the soil hypothesis would be some correlation between the local soil-chemistry at an impact site and the chemical composition of the resultant tektites. It must be assumed that climates have not changed appreciably since the time of impact since soil compositions would have changed accordingly. The Ivory Coast tektites are thought to have originated in an impact at Bosumtwi crater in Ghana[1]. If we can assume this area to have had a tropical or subtropical climate at the time of impact the soil of the impact site should have been enriched in Al_2O_3 and Fe_2O_3 and depleted in alkalis and CaO. Table 2 shows a comparison of these components with the average values. The alumina and iron oxide values are the highest for any tektites. The alkalis are not greatly depleted however. A second such comparison between source area and tektite is perhaps the Libyan desert glass for which no impact-site origin has been as yet proposed. The glass is close to pure silica in composition. This is the composition one would expect for a mature dune-sand such as that which forms the surficial cover over large parts of northern Africa. The rapid movement of these dunes may have buried and obliterated the impact site.

Table. 2. PARTIAL ANALYSIS OF IVORY COAST TEKTITES AND COMPARISON WITH AVERAGE TEKTITE

	A	*B*
Al_2O_3	14·60	13·13

THE BOTANIC GARDEN AND ITS FUNCTION IN MODERN SOCIETY

By Prof. N. F. ROBERTSON
University of Hull

HAVING lived for most of my life in close proximity to a botanic garden, and having recently moved to a city with no public botanic garden and with its University Botanic Garden at an early stage of development, I have been forced to think about the functions and future of botanic gardens. The gardens I have known have played a very large part in my life and I should like to think that any young person with botanical leanings could gain access to a well-run botanic garden.

There was a time, when medicine was concerned with plants, and later, when taxonomy and the exploration of the world for economic plants were in their heyday, that the making of a botanic garden was the proper work of a botanist. Later still, and in our own day, many botanists have found their interest in the functions of plants and in experimental work. The botanic garden lost active favour with these botanists and became the home of specialists—the taxonomist and horticultural plantsman. We have a situation to-day where the established botanic gardens flourish but where no new botanic gardens are being created unless we class as botanic gardens the large publicly supported horticultural gardens. I wish to suggest now that we are entering a new phase in the development of botanic gardens, that they have an ever-increasing part to play in the education of the public, of the professional botanist and in university teaching, and that there is a case for the establishment of more botanic gardens.

The great botanic gardens of the country need no justification. Expensive to maintain, they are visited and enjoyed by millions every year. In addition, they are great centres of research and form a training ground for horticultural plantsmen. It would not be sensible to try to recreate the Royal Botanic Gardens, Kew, or the Royal Botanic Garden, Edinburgh, in each of our great cities, but there is a real need for dynamic, named collections of plants in many of these cities. This need arises from the innate desire of people to determine the boundaries of their ignorance and to find some names as landmarks in the unknown field that interests them. It also arises from the needs of young men and women on the threshold of their careers. They may be born botanists, but the latent interest may not develop without opportunity and encouragement such as can be given by a good botanic garden. It is fashionable to decry the 'natural order bed'; certainly an attempt to cram the plants of the garden into an ordered arrangement without consideration of their horticultural or ecological needs is disastrous. On the other hand, it is a great revelation to the young botanist to see, for example, the range of variation in the Ranunculaceae, the repetition of leaf shape, the flux of genera, as *Thalictrum*, *Clematis*, *Anemone*, *Ranunculus*; the range of species in a genus and the ecological differentiation within species.

Apart from stimulating the young and aspiring botanist, the garden forms a reference collection for horticulturists, pharmacists, biochemists and other interested persons, and is one of the major tools of the taxonomist. It should also be æsthetically pleasing and a source of enjoyment for those who, while not experts, derive pleasure from the form and variety of plants. If this were all that a botanic garden did it would be as easy to justify as an art gallery or technical library in any sizeable town. One might well ask if the public parks do not already fulfil a part of the function of a botanic garden and inquire if this function could not be extended? In fact, some of the larger towns do run botanic gardens as part of the activities of the Parks Department, for example, Glasgow and Bath; other towns run specialized gardens which have part of the function of a botanic garden, for example, the Golden Acre at Leeds. These municipal efforts can play a very useful part in the provision of the facilities we desire. Parks superintendents of the smaller towns would be the first to admit, however, that they could, in attempting to develop a botanic garden, come up against formidable difficulties of lack of finance, of lack of support by the local authorities, and of lack of informed help from knowledgeable people. Good botanic gardens need constant care from botanical enthusiasts to keep them viable. Not every local authority parks department could provide the necessary botanical enthusiasm. Even where every portent is good, a botanic garden may not flourish under the supervision of the parks department because of the intrinsically different aims of park superintendents and curators of botanic gardens. The atmosphere of colour and interest produced in the park is quite different from the scholarly calm of the true botanic garden.

One of the strengths of the botanic garden is its association with active research work on taxonomic and other problems. As workers in different groups pass through the garden so collections will be increased and better documented, and the garden will appear always to contain novelties to the casual visitor. It is the scientific slant too which makes for much of the æsthetic quality of the garden. The practical ends of science, which should be the first concern of the garden, prevent it from having an immediate popular appeal, and so preserve some of the peace and informality which are an attraction to visitors. It could be said that when the botanic garden puts its visitors first and its plants second it loses much of its attraction.

If only a limited accretion of botanic gardens can be expected from developments of public parks, then the further developments must come in part from the universities. As new universities spring up, with departments of botany, they are the obvious places to nurture botanic gardens. If we can admit that such gardens should be established, we must inquire how big they shall be, how they shall be financed, who shall control them, and what services they shall give to the town they are in? To the first of these questions there is no answer; but I feel personally that the garden should be small, not large. Once a garden grows beyond a certain size, and some of the great gardens must, it loses the encompassed feeling which should be one of its pleasant features. Quite small gardens of an acre or two can show a remarkable range of plants. Where trees are to be included—and they should be—10–20 acres is better. Once past that size the garden becomes a showplace, and greater skill is required to ensure that the needs of the plantsman are not overlooked in the desire for display.

To the second and third questions I would answer that where possible the universities should finance and control the garden through their departments of botany. Having said that, one is faced with a number of problems. Botanic gardens, even small ones, cost a great deal of money to run. A small garden may easily use up one-quarter to one-half of the annual grant of the department of botany which it serves. This is a deterrent only in the sense that the garden should not be allowed to outgrow what the annual grant can accommodate. The actual sum spent on the garden will not be large in comparison with the sums spent on, for example, technological equipment, and the educational and research yield should be as great, if not greater.

If the university garden is to be open to the public the costs rise, if only by the provision of a policeman or garden ranger; questions of safety arise from such hazards as falling trees and poisonous plants, and it may be that the department of botany assumes a burden which may become intolerable financially and administratively. To overcome this difficulty it may be sufficient to arrange that the garden, while not open to the public, is open to a limited number of persons as ticket holders. The ticket holder would accept personal responsibility for any hazards which might befall him in the garden. If, in time, the garden grows to be a major cultural attraction in the town, then the town should share in the administrative expenses of opening the garden.

In new and developing institutions the policy decisions on the apportionment of land for the botanic garden must be firmly pressed home. The aspiring botanist is only too ready to accept the use of land at any price. This land may soon become the target of a take-over bid by the university building committee, with consequent upheaval for the department and discouragement for the garden staff. Another danger is that a specific area of land is not allocated but the botanists are given *carte blanche* to use the university grounds for planting purposes. This is a highly unsatisfactory procedure, for the botanists then become the prey of all the æsthetic pressure groups in the university. It is of the greatest importance that some knowledgeable member of the botany department should be in liaison with the horticultural and building staff of the university to make use of all the botanical and horticultural opportunities which present themselves. At the same time, the greatest evil that can befall a professor of botany is to be charged with the administrative care of the grounds of the university. The nearest analogy would be if the professor of physics were responsible for the supply of electricity to the university.

Very often a university garden will consist of an intensively cultivated small garden, exclusive to the department of botany, and a larger area which contains specimen trees and shrubs and which is part of, or which merges with, the grounds of a university hostel. This arrangement makes the opening of the garden to the public extremely difficult without an adequate police force because wardens of hostels are naturally averse to public access. It is possible to cite the freedom of access to the Cambridge and Oxford colleges; but there a very large police force is maintained by the discreet use of porters. If the university botanic garden is to play its part in providing an educational and æsthetic service to the town, then in new universities, and when changes take place in old universities, the department of botany should have a piece of land of adequate size under its sole control. Moreover, this should be associated with a policy of adequate provision of essential services for the future garden. Much money is wasted by the piecemeal extension of facilities, for example, electricity, water and heat for glasshouses and great savings can be achieved by planning large from the beginning.

If the botanic garden is to be a university-sponsored garden, and if, because of administrative and financial difficulties, it is to be of a semi-private nature, we have to consider the part the garden is to play in the educational policy of the department of botany. Unless the department and the garden are closely integrated in the teaching, the garden can become a 'white elephant'. If the taxonomic teaching in the department is limited, then the calls on the garden for teaching material will be limited and could be met by the provision of a service garden run cheaply for this limited purpose. Where, in the modern department of botany, there is the need for the growing of large numbers of plants for experimental work, then the additional cost of maintaining a collection of botanical interest is small and can well be justified. The student who comes from a department with a well-run botanic garden has an enormous advantage in that familiarity with a well-organized collection helps him to an ordered familiarity with the range of the plant kingdom. But the collection must be well organized and well displayed.

Few botanic gardens have tackled the problem of display. They still maintain the indigestible collections similar to those shown by the museums of thirty years ago. Nowadays, museums are careful to select material and to signpost it in such a way that a walk around a museum is an education. Botanic gardens must learn to select and to label too. This is particularly important in departments where formal taxonomic teaching is reduced to a minimum. In such departments the function of teaching must be undertaken by the well-documented garden. Moreover, the garden must display not only the taxonomic collection but where possible the ecological collection, the geographical and historical collection as well. The botanic garden should reflect the vitality of the department it serves, and one might almost say that the department can be made active by a well-run garden. In this age of specialization, when semantic barriers arise within the subject, the garden should be the integrating factor in the department of plant sciences, for such the modern department of botany is becoming. The biochemist should find the plant which interests him displayed in its taxonomic position, the taxonomist should find on the label an indication of the biochemical nature of its colour, its smell, its poisonous properties or a plant-physiological explanation of its ecological range, and so on. All will then achieve some appreciation of the point of view of other workers, and thus the garden would have a unifying influence.

Such a concept of the botanic garden demands skilled labelling, skilled growing, skilled display. It calls for a high degree of scientific ability on the part of the horticultural staff, and it demands a botanist who will devote time to the development of the garden. These are not easy things to achieve in short-staffed departments, but needs must first be formulated before they will be satisfied.

There have been two threads running through this article. The problem of the provision of more botanic gardens in general and the problems of the university botanic garden in particular. The conclusion is that we must encourage the public park to develop some sort of educational display of plants, that this may be better to have a horticultural bias because in this way it will command the enthusiasm of the parks staff. The second conclusion is that where possible the new (and sometimes the old) universities should develop a university botanic garden which can be open to the public but that where that is not possible the university should make its garden as freely available as possible to organized parties and should, by example and encouragement, help the parks department of the local authority to develop educational collections. Active botanic gardens should play an ever-increasing part in our cultural life.

OBITUARY

Sir James Wordie, C.B.E.

By the death of Sir James Wordie on January 16 both the University of Cambridge and the world of polar affairs have lost a valuable and experienced adviser. James Mann Wordie was born on April 26, 1889, in Glasgow, where he afterwards attended the Glasgow Academy and the University before moving on to the University of Cambridge in 1910 to continue his geological studies. From this time on, his life was centred about Cambridge for more than fifty years although his interests and contacts in Scotland continued.

He was elected Fellow of St. John's College in 1921 and was in turn supervisor, tutor, senior tutor, president and Master. Many men who passed through his hands during these years have since made their mark in various fields, including that of his greatest interest—polar research.

Wordie's interest in polar regions was stimulated by a visit to Alaska in 1913 and by contact in Cambridge with the geologists who had just returned from Scott's last expedition. He joined Shackleton's Imperial Trans-Antarctic Expedition of 1914–16 as geologist and senior scientist. After a year spent drifting in the ice, first in the ship, then living in tents on an ice floe after it was crushed, the party reached Elephant Island, where they spent the winter under their upturned boats while Shackleton made his remarkable boat journey to organize their relief. After return to England he served in the Royal Artillery until he was wounded and invalided home.

In 1919, Wordie joined the late Dr. W. S. Bruce as second-in-command of an expedition to Spitsbergen, which started a pattern, that has grown considerably in recent years, of university undergraduates taking an active part in summer expeditions to polar regions. In 1921 he led a small expedition to Jan Mayen Island, and in addition to geological studies he led the first ascent of Beerenberg (8,090 ft.). During the following ten years he led three more expeditions to East Greenland, which in addition to the immediate scientific results stimulated an interest in polar regions of men such as Sir Vivian Fuchs, the late Augustine Courtauld, P. D. Baird, of Canada, Prof. Gordon Manley and M. A. F. Barnett, of New Zealand. He continued with similar expeditions in 1934 and in 1937, travelling via West Greenland to Baffin and Ellesmere Islands. His last major trip was to the antarctic in the southern summer of 1946–47, when he visited the South Orkneys, the South Shetlands, where he had wintered in 1916, and Graham Land on behalf of the Colonial Office.

Even before the Second World War, but especially during and since the War, his advice and influence played a large part in the development of polar activities from the United Kingdom. He was a member of the "Discovery" Investigations Committee of the Colonial Office from its inception in 1923 until it handed over its responsibilities to the newly formed National Institute of Oceanography in 1949. He was a founder member of the Committee of Management of the Scott Polar Research Institute in 1926, and was its chairman during 1937–55. His lifelong interest in glaciers and sea ice led to his appointment as reporter for glaciology on the main planning committee for the International Geophysical Year as well as the vice-presidency of the International Commission of Snow and Ice and of the British Glaciological Society. He was chairman of the British Committee of the Norwegian–British–Swedish Antarctic Expedition 1949–52, and vice-chairman of the Committee of the Trans-Antarctic Expedition 1955–58. This expedition was initiated during his term as president of the Royal Geographical Society. It was also during this presidency that the first ascent of Mount Everest was made, and Wordie had played a part in the important decisions made by a joint committee of the Royal Geographical Society and the Alpine Club which led to this success. His last major task was that of chairman of the British National Committee for the International Geophysical Year and its various Antarctic Sub-Committees. His long-held belief of the accessibility of the eastern side of the Weddell Sea was well proved by the successful establishment of the Halley Bay Station by the Royal Society International Geophysical Year Antarctic Expedition, as well as the establishment of the Shackleton Base of the Trans-Antarctic Expedition.

For his own exploratory activities, Wordie was awarded the Back Grant (1920) and the Founder's Medal (1933) of the Royal Geographical Society, the Bruce Medal of the Royal Society of Edinburgh (1926) and the Gold Medal (1944) of the Royal Scottish Geographical Society. His administrative activities in polar affairs resulted in his award of the C.B.E. in 1947 and a knighthood in 1957.

James Wordie was a quiet and modest man, whose strength of character and shrewd judgment caused many responsibilities to be thrust on his shoulders. Throughout his life the support and interest of his wife as well as that of his three sons and two daughters provided an atmosphere against which he could give of his best in public responsibilities.

G. de Q. Robin

NEWS and VIEWS

Industrial Chemistry at Liverpool :
Prof. C. H. Bamford

Dr. C. H. Bamford, who has been appointed to the Campbell Brown chair of industrial chemistry in the University of Liverpool, is forty-nine years of age and was educated at St. Patrick's and King Edward VI Schools, and at Trinity College, Cambridge, where he graduated with first-class honours in 1934, and was awarded a Ph.D. in 1938 and an Sc.D. in 1954. He was elected a Fellow of Trinity College in 1937 and served as a director of studies in chemistry, Emmanuel College, Cambridge, during 1937–43. In 1941 he was awarded the Meldola Medal of the Royal Institute of Chemistry. During the War he was employed by Interservices Research Bureau with the Ministry of Economic Warfare. After the War he joined Courtaulds, Ltd., and was responsible for the fundamental research undertaken at the Maidenhead Laboratory, and in 1947 he was appointed head of the Laboratory. Dr. Bamford has served on committees of the Faraday Society and the Society of Chemical Industry. He has made visits abroad to Australia, the United States and the U.S.S.R. He has published three books and a large number of papers in chemical journals, mainly on photochemistry, polymerization and synthetic polypeptides and proteins.

Organic Chemistry at Liverpool :
Prof. A. R. Battersby

Dr. A. R. Battersby, who has been appointed to the newly instituted second chair of organic chemistry in the University of Liverpool, is lecturer in organic chemistry in the University of Bristol. He is thirty-seven years of age and was educated at Leigh Grammar School and the University of Manchester, where he graduated B.Sc. with first-class honours in 1946 and M.Sc. in 1947. He was awarded a Ph.D. of the University of St. Andrews in 1949. In October 1948 he was appointed lecturer in chemistry at the University of St. Andrews. He was awarded a Commonwealth Fund Fellowship in 1950 and studied for one year at the Rockefeller Institute, New York. The Fellowship was extended for a second year, which he spent at the University of Illinois undertaking research in biochemistry. He returned to the University of St. Andrews as lecturer in chemistry in June 1952, and in January 1954 was appointed lecturer in chemistry in the University of Bristol. He was awarded the Corday–Morgan Medal and Prize for 1959 by the Chemical Society.

Veterinary Research at the Wellcome Foundation, Ltd.:
Dr. R. F. Montgomerie

Dr. R. F. Montgomerie, director of veterinary research in the Wellcome Foundation, Ltd., has retired. Born on the Island of Bute in 1898, Dr. Montgomerie graduated from the University of Edinburgh and the Royal (Dick) Veterinary College in 1923. He was one of the first three veterinary surgeons appointed in the old Agricultural Advisory Service and was located at the School of Agriculture, University College of North Wales, Bangor, from 1924 until he joined the staff of the Wellcome Research Laboratories at Beckenham in 1937. In North Wales he quickly established a reputation by his work on diseases of sheep, and his introduction of carbon tetrachloride for the treatment of liver fluke disease earned him a world-wide reputation. This was enhanced by his study of the cause of sudden deaths in thriving lambs which had hitherto been ascribed to 'wool ball', but which he showed was due to enterotoxæmia, the condition thereafter being called pulpy kidney disease.

At the Wellcome Research Laboratories he led the team which has done so much to provide important sera and vaccines for the control of the common diseases of sheep. In his direction of the Wellcome Veterinary Research Station, Frant, he built up a research centre now widely known for its work on infertility in farm animals, the discovery of anthelmintics for the treatment and prevention of nematodirus disease in young lambs and the treatment of lungworm in sheep and cattle. His work was recognized by the National Sheep Breeders Association when, six months ago, he was made the first recipient of the George Hedley Memorial Medal for outstanding service to the sheep industry.

Mr. S. L. Hignett

Dr. Montgomerie has been succeeded by Mr. S. L. Hignett, head of the Wellcome Veterinary Research Station at Frant since it was established in 1943. Mr. S. L. Hignett has, like Dr. Montgomerie, been president of the British Veterinary Association (1959–60). He is probably best known for his work on bovine mastitis and infertility in farm animals.

The Australian Association of Clinical Biochemists

The following are the officers and State members of Council of the newly formed Australian Association of Clinical Biochemists: *President*, Dr. J. A. Owen; *Honorary Treasurer*, Dr. J. E. O'Hagan; *Honorary Secretary*, Dr. D. H. Curnow (Royal Perth Hospital. Perth, Western Australia); *Members*, Mr. M. J. Thomas (Queensland), Dr. F. C. Neale (New South Wales), Miss M. Bick (Victoria), Dr. R. S. Parsons (Tasmania), Dr. W. Roman (South Australia), Dr. G. A. Sarfaty (West Australia). The first annual general meeting and scientific meeting of the Association will be held in Sydney on August 21.

Laboratory of the Government Chemist Steering Committee

The Council for Scientific and Industrial Research has set up a Steering Committee for the Laboratory of the Government Chemist. The Committee will be under the chairmanship of Dr. B. K. Blount, deputy secretary of the Department of Scientific and Industrial Research. The members of the Committee will be: Prof. R. Belcher, professor of analytical chemistry, University of Birmingham; Mr. R. C. Chirnside, chief chemist and head of the Chemistry and Technical Services Division of the General Electric Co., Ltd.; Dr. D. T. Lewis, the Government Chemist; Mr. H. Wooldridge, deputy director (Stations Division), Department of Scientific and Industrial Research Headquarters.

The Laboratory of the Government Chemist is the oldest Government chemical laboratory; its origin dates back to 1842. It provides a wide variety of analytical and advisory services for Government

Departments. In addition, the Government Chemist has a statutory function as official analyst or referee in cases of disputed analyses under various Acts of Parliament. Responsibility for the Laboratory was transferred from H.M. Treasury to the Department of Scientific and Industrial Research in July 1959.

Exchange Programme in Nuclear Science

A BROCHURE, *The Exchange Programme in Nuclear Science*, issued by the International Atomic Energy Agency outlines the opportunities offered by the Agency for visiting professors and scientists, the courses organized and the research grants available (Pp. 36. Vienna: International Atomic Energy Agency, 1962). Information is included on the sponsorship of visits of scientists to foreign centres, the use of the mobile radioisotope laboratories and the financial arrangements. Lists of visiting professors, research grants made and training courses already organized and of the activities of the two mobile radioisotope laboratories are appended.

Glass Manufacturers' Federation Fellowship

THE importance of fundamental research to the modern glass industry is underlined by the endowment of a new research fellowship in the University of Sheffield by the Glass Manufacturers' Federation. Contributions towards the five-year fellowship have been subscribed by thirty-four firms in, or connected with, the British glass industry. Companies supporting the fellowship range in size from those employing more than 10,000 people, to small tradition firms of 100 or so craftsmen. The British glass industry ranks as the third largest glass producer in the world, but is probably one of Britain's smallest industries to support a distinct technology. The British industry played a direct part in the foundation, in 1917, of the Department of Glass Technology in the University of Sheffield, the first University school to undertake the study of glass technology as a separate applied science. This intimate connexion between the University and the industry has been maintained since that date, and Sheffield is still the source of the many glass technologists needed to-day by the highly mechanized glass industry. A feature of the Department is a strong postgraduate school, and the value of fundamental research is fully recognized by the industry. Further information concerning this fellowship can be obtained from Mr. J. Small, education officer, Glass Manufacturers' Federation, 19 Portland Place, London, W.1.

World Inventory of Historic Scientific Apparatus

A MEETING of the Commission de l'Inventaire Mondial des Appareils Scientifiques Historiques (president, A. Léveillé) was held in the United Nations Educational, Scientific and Cultural Organization Building, Paris, on January 24, and was attended by representatives of scientific organizations in Austria, Belgium, Czechoslovakia, France, Germany, Holland, Israel, Italy, Luxembourg, Poland, the United Kingdom, the United States and the U.S.S.R. The Commission is supported by the United Nations Educational, Scientific and Cultural Organization, and has also received financial aid from many Governments and national institutions. Research into the use and whereabouts of historic scientific apparatus is now being carried out in twenty-eight countries, and national inventories are being made. A working group has been set up to examine possible methods for the presentation of the results. At the next meeting of the Commission, to be held on October 1, the contributions from the various countries will be discussed with the view of incorporating the most important into a world inventory of historic scientific apparatus. Further information can be obtained from the Inventaire Mondial des Appareils Scientifiques Historiques, Palais de la Découverte, avenue Franklin D. Roosevelt, Paris 8e.

The Field Studies Council

THE annual report of the Field Studies Council, 1960–61 (Pp. 29. London: Field Studies Council, 9 Devereux Court, W.C.2, 1962), presented at the annual general meeting of the Council on February 16, includes the report of the Executive Committee and the reports of wardens at the field stations of Dale Fort, Flatford Mill, Juniper Hall, Melham Tarn, Preston Montford, Slapton Ley and Skokholm Bird Observatory. The steady progress of the previous 10 years was maintained and bookings increased again to 9,334, from 8,539 in 1960. Of these 5,183 were in biological and 3,006 in geographical and geological subjects. More than 2,000 applications had to be refused, and the executive committee is concerned at the number of last-minute cancellations and some failures to turn up for the courses booked. Of the individual attendances, 5,781 were from sixth forms, 782 from training colleges, 1,134 from universities and 1,249 amateurs. The membership is now approximately 4,000. comprising 1,050 corporate members and 2,950 individual members. Purchase of Dale Fort was completed in 1961, and in discussions with the Ministry of Education it has been agreed that the Ministry's grant should in future be for capital purposes and that the standard weekly fee should be raised by 10*s*. to £8 10*s*. It is hoped that the settlement will permit an adequate programme of capital improvements at the centres and that this will include a scheme for converting the High Stables at Melham Tarn. The opening of an additional centre is under consideration and during the year about £4,000 was spent on improvements to buildings and equipment.

British Technology Index

IN *British Technology Index* the Library Association has issued a valuable current subject guide to articles in British technical journals. The term 'technical' is interpreted generously, the 402 periodicals covered in the first issue (January 1962) including a number which ostensibly are scientific rather than technical (1, No. 1; January 1962. A Current Subject Guide to Articles in British Technical Journals. Pp. 70. Published monthly. London: The Library Association. Annual subscription for 11 monthly issues and bound annual volume, £15 15*s*. post free; 50 dollars, U.S.A.). Delays through the postal dispute excluded a further 120 periodicals which it was intended to cover in this issue. Entries are arranged alphabetically by subject, with adequate and common-sense cross-references, and are limited to title and bibliographical details. Among the features that should commend the *Index* to the industrial and technological user is the marked reduction in time-lag between publication of an article and its inclusion in the *Index*. In this connexion it is worth directing attention to the effective reply of Mr. L. L. Ardern in the *Library Association Record* for February to some questions asked about the response to the *Index* from industrial libraries in the United Kingdom.

Mental Health throughout the World

During June 1961 an International Study Group met at the Roffey Park Institute, Horsham, to discuss international aspects of mental health. Its primary function was to make a broad survey of the progress being made in the many aspects of mental health field throughout the world. An attempt was made to cover the spectrum of interests from research and care of the mentally sick at one end, to international relationships at the other (*Mental Health in International Perspective*. Pp. 84. London and New York: World Federation for Mental Health, 1961).

Causes of Deafness in Schoolchildren

A total of 270 children born in Northumberland and Durham during the years 1945–54 are receiving education in schools for the deaf. This represents an incidence of severe deafness of 0·7 per 1,000, the same as the national incidence. Dr. M. E. Barton, Dr. S. D. Court and Dr. W. Walker of the Department of Child Health, Durham University Medical School, King's College, Newcastle upon Tyne, have studied the early medical history and family background of these children (*Brit. Med. J.*, 5275; February 10, 1962). Twenty-five per cent were classified as having hereditary deafness, in 25 per cent deafness followed meningitis or some other infection, but in 50 per cent the cause of deafness was unknown. Of the unexplained cases there was a history of maternal rubella during the first three months of pregnancy in two instances, while two more of the children had suffered from severe hæmolytic disease of the newly born. Of the remainder, 21 per cent were 'premature' infants, 7·6 per cent having a birth weight of 4 lb. or less. Only 18 per cent of the premature infants gave a history of severe jaundice, and it would appear that prematurity even in the absence of jaundice may be an important cause of deafness.

Influence of Diet on the Incidence of Atherosclerosis

Dr. M. Toor, Prof. A. Katzir and Dr. I. Agmon have carried out an investigation of the socio-economic conditions, diet and serum cholesterol-levels of 2,680 immigrants to Israel from Eastern and Western countries belonging to different social groups (*Dapim Refuiim*, 11, No. 1; January 1962). The lowest serum cholesterol values were found among 'recent' Yemenites, the least fortunate economically and with an imbalanced intake and the lowest fat content. Higher cholesterol values were found among the early Yemenites and European manual workers whose diet was richer in calories and a percentage of calories derived from fats. In middle class Europeans the serum cholesterol-levels were still higher. A positive correlation was found between these serum cholesterol-levels and morbidity and mortality from atherosclerosis for the different groups investigated. The results support the assumption that atherosclerosis is a disease of lipid metabolism in which diet is a dominant factor.

Schistosomiasis

The latest issue of *Phoenix* is concerned with schistosomiasis or bilharziasis (1, No. 3; December 1961. *Bilharziasis/Schistosomiasis*. Pp. 16. Ann Arbor, Michigan: Michigan Memorial–Phoenix Project, The University, 1961). Estimates of the number of people afflicted with schistosomiasis range from 114 million to 200 million. These infested people live principally in agricultural communities in Asia, Africa and South America. In many areas, particularly Asia, schistosomiasis is also a disease of animals, thus adding detrimental economic effects to its human toll. Because of the growing number of countries in which the disease is known to exist, and because of the extension of the snail habitats in these countries and the growing number of infested people, schistosomiasis has become one of the worst diseases in the world. The interest of the Phoenix Project in schistosomiasis stems from a research programme supported by the Project and conducted in the Phoenix Memorial Laboratory, University of Michigan. The investigators are using radiation from a cobalt-60 source in an attempt to create a vaccine that will provide immunity to the disease.

Paralytic Rabies in Greenland

For at least a hundred years epizootics of a disease resembling rabies have raged among the sledge dogs of Northern Greenland. In 1859 Dr. N. Rudolph, medical supervisor of the Upernavik district, described the clinical picture in dogs of extreme exhaustion, hydrophobia, abundant secretion from the mouth, and weakness of the hind legs. In the initial stage the disease was clearly epidemic. Between 1864 and 1865 a similar outbreak occurred in the northern districts. In 1908 Mr. S. R. Hjortlund described a highly contagious and deadly epizootic in dogs: in most cases the disease ran a quiet paralytic course, but a few dogs were aggressive. The cause of the disease was never established, but it was noted that often the disease broke out a few days or weeks after fights between dogs and 'mad' polar foxes. Because rabies is widespread among arctic foxes and other animals in Canada, it was assumed that Canadian foxes traversing the icebound Davis Strait had transmitted the disease to Greenland foxes, which in turn had transferred it to the dogs. This, however, was never proved, and only recently have the combined efforts of American and Danish laboratories shown that the canine disease is true rabies. In recent years canine epizootics have been numerous. Four outbreaks between 1957 and 1960 played havoc among the dogs in northern Greenland, and nearly caused famine among the Eskimos, to whom the dogs are indispensable. All the affected dogs died—a fact suggestive of rabies—and extensive vaccination of the dogs against rabies rapidly stopped the spread. Despite the recurrent canine epizootics, not a single human case of rabies has previously been reported from Greenland, where adults, and especially children, are often attacked and severely bitten by aggressive dogs. Prof. H. C. A. Lassen, of the University of Copenhagen, now describes an unequivocal case of human rabies from Greenland (*The Lancet*, 7223; February 3, 1962). The disease ran an exclusively paralytic course.

New Zealand Barrier Island Study

The Little Barrier Island (Hauturu to the Maoris) is a nature reserve lying some 50 miles north-east of Auckland. Bulletin 137 of the New Zealand Department of Scientific and Industrial Research provides an admirable and detailed account of the Island accompanied by clear, well-drawn and relevant maps (*Little Barrier Island* (*Hauturu*). Compiled by W. M. Hamilton. Second edition. Pp. 198+4 maps. Wellington: Government Printer, 1961. 30*s*.). The story of the nature reserve is quite interesting. By 1896, the year the reserve was established, about one-third of the natural forest had been modified by burning, tree-felling or grazing and there was considerable danger that certain birds adapted to the forest habitat, already rare, might become extinct. The Island is now one of the few remaining large areas of native forest in New Zealand and one bird, the stitchbird (*Notiomystis cincta*), is believed to be unique to the area. The Bulletin provides an admirable account of the various elements of the environment—geology, physiography, soils, fauna and flora together with an introductory section on the Maori occupation. Hauturu is a dissected volcanic cone, probably Mid-Pleistocene in age, rising to a height of 2,370 ft. Andesites and andesitic breccias are the predominant rock types although there are small areas of Holocene (Flandrian) deposition. The vegetation shows a vertical zonation modified by the destruction that took place before 1896. These areas are rapidly reverting to Kauri forest (and other broad leaf communities) through transition phases of heptospermum forest. The forest areas provide the habitat for many native (and some introduced) birds. The main disturbing factor is the presence of cats although every attempt is being made to eliminate these. Their effect on the bird population is, however, considered to be slight. Some species have been introduced to the Island, one of which, the North Island Kiwi, seems to have been successful. There are also several curiosities including the tuatara and *Spenceriella gigantea*, a 4½-ft. long earthworm. The Bulletin, naturally, is mainly of local interest but it should have a wider appeal to geomorphologists and ecologists for the accounts of the dissected volcano and the vegetation pattern.

Cosmology and Meteorology in the U.S.S.R.

A NUMBER of articles dealing with the various aspects of recent cosmic flights was published during 1961 in the Soviet popular scientific journal *Priroda*. These include: 8, 7, 15, 16; 9, 9, 24, 54, 75; 10, 23, 32; 11, 9. According to V. P. Petrov and A. A. Sochivko (*Priroda*, 7, 25; 1961), future development of cosmic flights may help to map out the cosmic background responsible for the changes in terrestrial weather. Special space stations, regularly distributed around the Earth and to be called 'geophysical sputniks', will carry special equipment suitable for such a task. The recorded data will be transmitted continuously to the terrestrial receiving stations. In a short article, B. I. Vronsky (*Priroda*, 9, 90; 1961) describes the five meteorites (locality marked on a sketch map) which have recently been found in the north-east Siberian territory. They are: (1) Susuman, 1937; (2) Mal'dyak, 1939; (3) Burgavli, 1941; (4) Yudoma, 1946; (5) El'ga, 1959. The last-mentioned meteorite, El'ga, found deep down in auriferous gravels (see also *Nature*, 187, 648; 1960), consisted essentially of nickel–iron with 10–15 per dispersed stony chondrules, the main constituents of which are alkali feldspar and clinopyroxene, with small amounts of glass and maskelinite. The metallic part, the chemical analysis of which is given, is composed essentially of kamacite and tænite. On February 18, 1961, Soviet and visiting astronomers had the chance of observing a full eclipse of the Sun, and this event gave the physicists the opportunity of trying a new method of insemination of clouds by granular 'dry ice'. These experiments, carried out in the Crimea, were very successful. The details of the process of artificial cloud dispersion are described by V. V. Vyal'tsev (*Priroda*, 11, 79; 1961.

Hydrology and Water-power in the U.S.S.R.

A PROJECT of linking some of the rivers flowing into the Arctic Ocean with the River Volga is briefly outlined by G. L. Sarukhanov (*Priroda*, 7, 53; 1961) and also by N. S. Buyakovsky and M. I. L'vovich (*Priroda*, 6, 58; 1961). The main necessity is the steadily lowering level of the Caspian Sea, producing a crisis in navigation and fisheries. It is suggested that the upper reaches of the Rivers Pechora and Vychigda (a tributary of Northern Dwina) be dammed so as to transfer 40 milliards cubic feet of water annually into the Rivers Kama and Volga. This would make possible the formation of large water reservoirs and improved river navigation. Ya. A. Mazover and V. K. Saveliev give a summary account of the prospects for the wider utilization of water and fossil fuel powers in the U.S.S.R. (*Priroda*, 10, 49; 1961). The important feature in the problems of energetics in the European part of the U.S.S.R. is that consumption is above reserves, while in the Asiatic part consumption is well below reserves. Gigantic hydroelectric installations, like those of the Angara–Yenisey, will in time enormously increase the output of energy. Transport of fuel and transmission of energy from regions of potentially low consumption to regions of high consumption may solve this discrepancy. Local development of industries will also tend to restore the balance of energetics. In any event, it is anticipated that there will be a considerable flow of energy westwards from central Asia and western Siberia.

Non-Pressure Methods of applying Wood Preservatives

RECORD No. 31 of Forest Products Research, issued by the Department of Scientific and Industrial Research, includes concise descriptions of applying preservatives to timber by brushing, spraying, dipping, steeping, and the hot and cold open-tank and diffusion processes (Record No. 31. *Non-pressure Methods of applying Wood Preservatives*. By J. Bryan and D. F. Purslow. Pp. iv+14+8 plates. London: H.M.S.O., 1961. 2*s*. 6*d*. net). Immersion treatments ensure more complete contact between the wood and preservative, and thus can be more effective than other non-pressure methods. Their effectiveness depends to a certain extent on the period of immersion, but better results can be obtained by the well-known open-tank process. The plates illustrate the varying degrees of penetration obtained and two examples of an open-tank. Simple and readily understood graphs show rates of absorption for different preservatives by steeping and by double heating open-tank process. This useful booklet will be appreciated by those requiring an understanding and a practical guide to the subject.

Resinification of Knots in Radiata Pine

IN New Zealand it has been found that during the kiln drying of radiata pine, the checking of intergrown knots is much worse in those which have a low content of resin and are large. Therefore, in order to try to improve the quality of kiln-dried radiata pine so far as knots affect it, two practical possibilities are considered in *Forestry Research Notes*, No. 28, issued by the New Zealand Forest Service, namely, the increased resinification of knots and artificial pruning treatments (*The Resinification of Knots in Radiata Pine*. By J. Maddern Harris. Pp. 10. Wellington: Government Printer, 1961). Experiments dealing with the latter are being carried out, but this research note deals mainly with an examination of all the variables which might affect the results of pruning experiments and other treatments and an investigation of the resinification of knots as a process associated with the ageing of the stem. The results of the study show that the normal course of resinification can be regarded as beginning in one of two ways, depending on whether a branch dies before heartwood starts to form in the stem or heartwood formation has begun. The observations and analysis of the results are well described and discussed. They form a practical basis to take the subject a step further, that is, to relate it to time and height of pruning and, of course, to economics. This paper is a very useful contribution to the questions of when, how and to what extent resinification of a knot takes place.

Enrico Fermi School of Physics: Summer Courses

The International School of Physics "Enrico Fermi" is organizing five summer courses in physics at the Villa Monastero, Varenna sul Lago di Como. The subjects of the courses will be: (1) space exploration and the solar system, June 4–16; (2) advanced plasma theory, July 9–21; (3) elementary particles, July 23–August 4; (4) dispersion and absorption of sound by molecular processes, August 6–18; (5) star evolution, August 20–September 1. Further information can be obtained from Prof. S. Olbert, Massachusetts Institute of Technology, Cambridge 39, Massachusetts (course 1); Prof. M. Rosenbluth, General Atomic Division, General Dynamics Corporation, P.O. Box 608, San Diego 12, California (course 2); Prof. M. Conversi, N.P. Division, CERN, Geneva 23 (course 3); Prof. D. Sette, Cattedra di Fisica, Facoltà di Ingegneria, Via Eudossiana 18, Rome (course 4); Prof. L. Gratton, Laboratori Nazionali di Frascati, Casella Postale N. 65, Frascati, Rome (course 5).

University News: London

The title of professor of experimental physics has been conferred on Dr. W. Ehrenberg and that of professor of electrochemistry on Dr. D. J. G. Ives, in respect of their posts at Birkbeck College.

Dr. A. Cameron has been appointed to a readership in mechanical engineering, tenable at the Imperial College of Science and Technology, and Dr. K. Fotherby has been appointed to a readership in chemical pathology, tenable at the Postgraduate Medical School. The title of professor has been conferred on Dr. W. Bowen Bonnor (mathematics) in respect of the post held by him at Queen Elizabeth College. The titles of reader have been conferred on: Dr. P. G. Walker (chemical pathology) in respect of the post held by him at the Institute of Orthopædics; Dr. A. F. Cobbold (experimental physiology) in respect of his post at St. Thomas's Hospital Medical School; Dr. A. E. Kellie (biochemistry) in respect of his post at the Middlesex Hospital Medical School. Dr. J. F. Fowler has been appointed reader in physics at St. Bartholomew's Hospital Medical College.

Announcements

Among the newly appointed life peers announced on March 29 is Sir Alexander Todd, professor of organic chemistry in the University of Cambridge, and chairman of the Advisory Council on Scientific Policy.

Dr. Jean-Pierre Barrat, of the University of Caen, has been awarded the Adolph Lomb Medal of the Optical Society of America. The Medal is awarded to a person under thirty years of age who has made "a noteworthy contribution to optics".

The Zoological Society of London has awarded the Edward Forbes Medal for scientific merit to Dr. Arthur James Cain, of the Department of Zoology, University of Oxford, and to Dr. Robert Aubrey Hinde, of the Department of Zoology, University of Cambridge. The Medals—awarded to persons under forty years of age for distinguished work in zoology—will be presented by H.R.H. the Duke of Edinburgh, president of the Zoological Society of London, immediately following the annual general meeting of the Society, which will be held on April 27.

The office of the International Society for Tropical Ecology has moved from Allahabad to Varanasi (India). All communications should be addressed to Prof. R. Misra, Banares Hindu University, Varanasi, India.

A meeting of the British Society of Soil Science will be held at the London School of Economics, Houghton Street, W.C.2, during April 16–18. There will be three sessions: (*a*) productivity and soil type; (*b*) microbiology of podzols; (*c*) micro-organisms in relation to nutrient availability in soil. Further information can be obtained from Dr. D. V. Crawford, University of Nottingham School of Agriculture, Sutton Bonington, Loughborough.

The National Engineering Laboratory, East Kilbride, is holding open days during May 2–4. Developments on show in the field of mechanical engineering will include: the application of air-lubricated bearings to machine tools; research on the production of new materials by the application of very high pressures; facilities for research on creep of metals; new automatic measuring techniques; further data on the cold extrusion of steel; advances in pump and fan design. Further information can be obtained from the Director, National Engineering Laboratory, East Kilbride, Glasgow.

A symposium on "The Protection of Structural Steel" will be held in the University of Birmingham on April 18. The programme will include: the hot-dip galvanizing of structural steel; the properties of hot-galvanized steel; galvanized structures for power transmission; the use of hot-galvanized steel in building; the design and protection of tubular steel structures; the application and uses of zinc spraying; economic aspects of protection. Further information can be obtained from the Zinc Development Association, 34 Berkeley Square, London, W.1.

Errata. In the article entitled "Fatty Acids in Recent and Ancient Sediments and Petroleum Reservoir Waters" (*Nature*, 193, 744; 1962), by J. E. Cooper, the fifth sentence in the second complete paragraph on p. 746 should read: "Intermediates of this type derived from even-numbered acids could react to give a mixture of odd-numbered acids and paraffins as a product".

In Table 1 of the communication entitled "Inhibition of Dopamine β Oxidase by Adrenalone", by M. Goldstein and J. F. Contrera (*Nature*, 192, 1081; 1961), cols. 1, 2 and 3 should be headed Dopamine, Adrenalone and Epinine, respectively; the last insertion in col. 2 should read 1·2, and the second in col. 3 should read 3·2.

SCIENCE IN PARLIAMENT

On February 27 the Parliamentary Secretary for Science, Mr. D. Freeth, answered a series of 22 questions in the House of Commons dealing with a wide range of scientific matters.

Concerning the 15 research stations and 52 research associations (47 of which have research stations) to which the Department of Scientific and Industrial Research made grants, Mr. Freeth stated that while the siting of co-operative industrial research associations and laboratories was primarily a matter for the industrial members of the associations he would look into the matter of location.

As regards research into the Turner system for constant-flow traffic signals, it was expected that a pilot scheme for this or a similar system would be tested later in the year on the Road Research Laboratory's research tract at Crowthorne.

The distillation of sea-water was an established industrial process, and British-made equipment was among the best in the world. Compared with normal sources of supply in Western Europe, however, distilled water was expensive, and any extensive use for industrial purposes in Britain was unlikely, except in very special circumstances where it would be economic. A considerable amount of research was being undertaken by industrial companies.

To questions regarding the establishment of a social sciences research council, Mr. Freeth said that the Minister for Science was consulting the Research Councils and Government Departments and the University Grants Committee on the views of the Council for Scientific and Industrial Research. Contributions from the latter in one sector of this field had nearly doubled during the past two years, and he did not agree that the establishment of a further research council was the only way to secure a substantial increase in research in the social sciences.

The Minister for Science had asked the Department of Scientific and Industrial Research for its views on the proposals in the Toothill report on research and development contracts for Scottish industry.

About 15 scientists and engineers from the Atomic Energy Authority will participate in the British experimental nuclear test in Nevada, but no decision had yet been taken about holding tests at Christmas Island.

As to the use of operational research and social survey methods in administration, Mr. Freeth said that the Industrial Operations Unit of the Department of Scientific and Industrial Research had recently co-operated with the Ministry of Health, the Royal Mint and the War Department. Social survey methods were mainly used by the Social Survey Division of the Central Office of Information.

As regards the exhaust from Diesel-powered vehicles, Mr. Freeth said that the Warren Spring Laboratory of the Department of Scientific and Industrial Research had not found any suitable means of recovering smoke from such exhausts, but would examine any device for this purpose that came to its notice. Mr. Freeth repeated an earlier statement that the real remedy lay in correct operation and maintenance of the engines. Concerning the future programme of the Economics Section in the headquarters office of the Department of Scientific and Industrial Research, Mr. Freeth stated that this was currently under discussion; 374 students graduated in Scotland with honours degrees in science and 105 with honours degrees in technology in 1959–60.

Research was proceeding at the National Physical Laboratory on noise in industry from motor-vehicles and from aircraft, including jet aircraft; at the Building Research Station, on noise in buildings; and at the National Engineering Laboratory, on noise from machines. Extensive experiments had been made on a subjective assessment of motor-vehicle and aircraft noise, and surveys were in progress on noise in communities and in industry. The report of the Wilson Committee on the problem of noise was expected before the end of the year.

In a written answer on February 27, Mr. Freeth stated that research on the structure, function and metabolism of normal and diseased muscle, which might assist in elucidating the cause of, and the most effective methods of treating, muscular dystrophy, was supported from public funds by the Medical Research Council and by university and hospital departments.

The British Commonwealth Scientific Committee met in the United Kingdom in 1960 and would meet in India during November–December, 1962.

British Satellite Research

Replying to a question in the House of Commons on February 26, the Minister of Aviation, Mr. P. Thorneycroft, said that the cost of continuing the development of the *Blue Streak* missile as the first stage of a satellite launcher to the end of January 1962 was approximately £6·1 million, and the total cost of the proposed three-stage launcher had been estimated at about £70 million, of which the United Kingdom would pay £26 million. The objects of the project were to develop a heavy launcher capable of putting satellites into orbit for scientific and commercial purposes to disseminate associated technical knowledge, and by pooling scientific and technical resources to permit Europe and Australia to play a full part in the peaceful exploitation of space. On February 27 the Parliamentary Secretary for Science said the space research programmes, for which the Minister for Science was responsible, employed 17 qualified staff early in 1960, 27 in January 1961 and 25 in January 1962, while 20, 32 and 40, respectively, suitably qualified staff in Government departments were engaged in similar experiments or supporting work, or the observation and tracking of satellites.

Expanding the Field of Education

In a written answer in the House of Commons on February 27, the Minister of Education, Sir David Eccles, announced that from April 1, 1962, all the colleges of advanced technology would be administered by independent governing bodies and would receive direct grants from the Ministry. The colleges now had nearly 9,000 full-time students and had arrangements in hand to increase this number to 15,000 by the mid-1960's. He was now authorizing the colleges to plan for an expansion to 21,000 places, the date depending on decisions still to be taken regarding the rate of public service capital investment after 1963–64. Capital expenditure on educational building in 1963–64 would rise to £130 million as against £125 million in 1962–63, including starts of £55 million for major school-building projects, with a special priority for the provision of science accommodation at secondary schools, amounting to £7·5 million during 1963–64. The expansion of teacher training colleges by 24,000 places would proceed as planned, and the further education programme, calling for £17 million in 1963–64, also remained unchanged. The Youth Service was authorized to start £7 million of work in the first three years after the Albemarle Report and the programme for 1963–64 would be £3 million. On March 1, Sir David said that he understood that conversations were about to commence between the principals of the colleges of advanced technology and the Central Council for University Admissions. Of 55,000 full-time overseas students in the United Kingdom, 12,000 were in universities, 13,000 in technical colleges and 1,400 in teacher training institutes.

Education of Commonwealth Scholars in Britain

In reply to a question in the House of Commons on February 15, the Joint Under-Secretary of State for Commonwealth Relations, Mr. B. Braine, said that the Government was considering various means by which the Commonwealth Scholarship Commission could extend a substantial number of scholarships for a third year without reducing much below the present level the number of new scholarships to be offered annually. Last year, Britain spent £122,000 on the scholarships plan, and it was estimated that this year £330,000 would be spent, and next year £490,000; the Government was unable to increase its total financial contribution to Commonwealth educational co-operation at present. Asked as to progress with the scheme for increased residential accommodation for overseas students, Mr. Braine said that, up to February 12, twenty-six projects, involving 1,113 additional beds, had been approved in principle; but in spite of this response from voluntary organizations, the need for new hostels was still very great, and the British Council would be pleased to advise and help other organizations which contemplated providing them. The approved scheme, designed to supplement the efforts of voluntary bodies, provided for 557 beds in London and 556 beds outside London. A total of 153,000 copies of university text-books and 155,000 copies of other books had been printed to date for distribution through the publishers to Commonwealth and other countries in Asia, and a further 241,500 text-books and 469,500 other books were in production.

Higher Education in Colleges of Technology in Britain

In a written reply in the House of Commons on February 12, the Minister of Education, Sir David Eccles, gave the number of students enrolled in January 1962 in the 108 courses leading to the Diploma in Technology as 6,201; of these, 1,624 were in electrical and 1,441 in mechanical and production engineering; 798 in chemical technology; 558 in physics; 332 in aeronautical engineering; 304 in civil engineering; 268 in mathematics; and 224 in chemical engineering. Of the 2,360 first-year students, 1,729 qualified for entry by the General Certificate of Education and 561 by the Ordinary National Certificate. On February 14, Sir David gave the number of full-time teachers in technical colleges in 1960–61 as 19,847, with 52,435 part-time teachers; these figures compare with targets of 18,615 and 46,939 in the Willis Jackson Report. As regards action on the White Paper on technical education of January 1961, Sir David stated that the whole pattern of part-time courses in engineering had already been approved and a new general engineering course and an important new engineering technician course started last autumn. Agreement had been reached on the common Ordinary National Certificate and Diploma courses in engineering which would form a basis for later specialization, for example, in mechanical, electrical, chemical or aeronautical engineering, and discussions were proceeding about possible new courses in mining, textiles and applied science.

Road Safety in Britain

In moving the second reading of the Road Traffic Bill on February 28, the Minister of Transport, Mr. E. Marples, said that the Bill made a small contribution to road safety. During 1960, 6,970 people were killed and 347,551 injured on the roads and the cost to the nation was estimated at £229 million. Mr. Marples referred to an experiment to be tried at three places in London with a light signal of a new design and also to measures in education, especially with adults, which were being discussed with the Road Research Laboratory.

As regards provisions for enforcement, the first part of the Bill dealt with driving offences and with drink, and was intended to reduce the number of accidents which could be attributed to alcohol.

In replying on the debate the Parliamentary Secretary to the Ministry, Mr. John Hay, said it was proposed to tackle the problem of the education of adults in road safety by appointing a special research team, consisting of technical experts, and including some with experience in psychology and related matters. The team would study first the human factors involved in road-user behaviour and accident situations and, secondly, explore the means of influencing this behaviour most effectively. Its task would be to ascertain what causes accidents and to examine the matter from a personal point of view. The details of these proposals were being explored by the Ministry and the Road Research Laboratory.

It was proposed to set up two or three experimental road-safety teams in selected areas to take an overall view of road accidents and propose combinations of road-safety measures in their areas. The teams would familiarize themselves with the accident pattern of their areas and make specific proposals to the authorities concerned. They would not be executive bodies.

Mr. Hay reiterated that the overall objective of the Bill was to try to save lives and to prevent accidents, and he was emphatic that in dealing with dangerous or negligent driving the fact that disqualification for a professional driver involved deprivation of livelihood should not be allowed to affect the penalty imposed.

Control of Toxic Chemicals

In a written answer in the House of Commons on March 8, the Parliamentary Secretary for Science, Mr. D. Freeth, stated that the Research Councils were concerned in general with those recommendations of the Research Study Group on toxic chemicals in agriculture which related to fundamental research: those relating to surveys and inquiries would mostly be the concern of the Agricultural Departments. The Research Councils proposed to continue their already substantial research in the fields mentioned in the report and to extend it, so far as resources permitted, where fruitful results appeared likely. The various tasks were shared between them in accordance with their normal interests. Research into problems bearing on the toxicity of agricultural chemicals to human beings fell to the Medical Research Council while the Agricultural Research Council was responsible for basic research on chemical hazards concerning farm crops, animals and soil, and the Nature Conservancy was responsible for research relating to the effects of agricultural chemicals on wild life and the natural environment. Research into improved methods of determining residues of toxic chemicals in foodstuffs and animal tissues was the responsibility of the Government Chemist in the Department of Scientific and Industrial Research. Certain problems were of concern to two or more research councils, and the Agricultural Research Council was setting up a scientific committee with Prof. A. C. Frazer as chairman to keep all relevant research under review and report progress.

Civil Science by Government Agencies

In answer to a question in the House of Lords on March 7, the Minister for Science, Lord Hailsham, said that the Government had decided to review the existing organization for the promotion of civil science by Government agencies. This review, which would be concerned mainly with issues of administrative organization and the machinery of Government, would take full account of the views expressed by the Advisory Council on Scientific Policy, and advice would also be sought from scientists both inside and outside the public service. Lord Hailsham undertook to inquire into the consultation of representatives of industry also.

THE COLOMBO PLAN

TENTH ANNUAL REPORT

THE tenth annual report of the Consultative Committee on the Colombo Plan for Co-operative Economic Development in South and South-East Asia* includes a short chapter on technical co-operation, which has been an integral part of Colombo Plan operations since 1950 and provides a framework for exchanging technical assistance between participating countries. Excluding some 6,840 who went to the United States in 1950–58 before the United States became a formal participant, technical co-operation under the Plan enabled 19,533 men and women of the region to visit other countries to acquire specialized knowledge, aptitudes and experience enabling them to increase their contribution to the development of their own countries and has filled gaps in the technical knowledge in the region by providing experts whose influence extends far beyond the technological field. Despite the achievements of the past ten years, however, the importance of technical co-operation in overcoming the shortage of trained manpower has in no way diminished. The needs of countries in the area for trained men and women remain very great and frequently the progress of development has brought new requirements for the expansion of technical skill.

Total expenditure on technical assistance by all members of the Plan in 1960–61 exceeded £20 million, that on the provision of training places substantially increasing while that on equipment almost doubled, to reach £5·6 million. New training awards increased from 4,268 to 4,417, and the number of new experts provided from 535 to 786. Training capacity is now much greater than it was in 1950, particularly at the higher professional levels, and thirteen of the twenty-one member countries are now among those who in the past ten years have provided 1,852 training places within the area. A survey during the year revealed a serious gap in trained manpower between professional technologists and skilled craftsmen but also indicated that facilities for many specialized types of training at the latter level are not fully utilized, and the need for constant endeavour to find improved methods and procedures of rendering technical assistance.

Even in this chapter of the report reference is made to the urgency which the growth of population in the area over the past decade has brought to the area, and this is one of the dominant notes of the review of economic progress during the past ten years and of the task ahead which are probably the two chapters of most outstanding interest in the report. Since the Colombo Plan commenced, the population of South and South-East Asia has increased by 150 million, and by 1980 it is expected to approach 1,000 million as against the 720 million expected for 1970 in 1950—a figure which was reached in 1960. The central fact of this situation is a sharp rise in the rate of natural increase, partly due to the very success of the Colombo Plan in such fields as health and medicine. The difficulties faced by these countries exceed any experienced in this field by the industrially advanced countries, and against this background the growing pressures of the peoples of the region for higher living standards and the extent of the progress which can be achieved can affect political stability.

It is not surprising, therefore, that the report singles as the dominant achievement of the past ten years under the Colombo Plan the awareness growing throughout the area and among the countries outside of the urgent need for more rapid development and for efforts to be directed towards that end. National income has indeed grown almost continuously, particularly since 1953, and most countries have recorded substantial gains in overall output as well as in important sectors, but frequently the rapid increases in population diminished the measurement of gains on a *per capita* basis. Invariably, the area-wide attack on poverty and low living standards through economic development has been pressed, and the forward movement of the economics of the area is clearly evident.

Agricultural production—the mainstay of the area's economy—has significantly increased both in terms of total production and in terms of yield per unit of cultivated land, and the index of agricultural output increased by about 12·5 per cent, compared with an average world increase during the same period of about 15·5 per cent. The production of rice, the staple food of the area's population, increased by about 40 per cent to more than 108 million tons in 1960, and that of maize by more than 30 per cent. Output of petroleum increased from 10·8 million tons to 26·5 million tons, of coal from 35 million tons to more than 54 million tons; steel production from about 1·3 million tons to more than 3 million tons; and of cement from less than 6 million tons to 10·8 million tons, while diversification is gradually being achieved both in agriculture and industry. Illiteracy is being reduced, and most countries aim at establishing universal primary education in the foreseeable future, while secondary and higher education are being rapidly promoted. Malaria is being eradicated, and health programmes have helped to mitigate the ravages of influenza, tuberculosis and other epidemics

R328

Looking at the task ahead, particularly in the light of the increase in population during the decade 1950–60 from 595 million to 743 million, or 1·5 times that of the increase during 1920–50, the report points out that while the objectives set out in 1950 have been shown to be correct, the task has proved even more formidable than was expected. The peoples of the region are aware that progress will continue to depend above all on their own efforts and determination and that external assistance, however massive, cannot replace those efforts. Apart, however, from this continuing need for popular understanding and support, the Governments of the region will continue to be faced with the need for resolute action to raise the standards of living, and in this priorities present special difficulty. The precise balance between investment in agriculture and in industry, of priorities within the agricultural and industrial sectors, between investment and consumption, between a lower level of education and training for the many and a higher level for the comparatively few will never be easy to determine. Beyond this there remains a challenge to the more developed countries within the limits of their resources to help the less-developed countries to help themselves. In doing so they will make the greatest possible contribution to the development and welfare of the region, but while external aid will remain an important factor in determining the degree of economic progress, the more-advanced countries must continue to adapt their methods and approach to changing circumstances. There are no simple solutions to the many problems that arise and progress can only be made as difficulties are tackled in a continued spirit of goodwill and co-operation and on the basis of growing appreciation and understanding of each other's difficulties. The second, and largest, part of the report outlines the progress made in the individual member countries of the Plan in 1960 and during the decade 1950–60, while in Part 3 are outlined some contributions to economic development in South and South-East Asia made by individual countries. United Kingdom Government expenditure on capital and technical assistance for development in South and South-East Asia during 1960–61 totalled £35·9 million, bringing the total of such expenditure under the Plan to £182·78 million, with outstanding commitments at June 30, 1961, of £84·13 million (including the whole of the £20·8 million contribution to the Indus Basin Development Fund) to be paid over the period 1960–72. Expenditure of £1·14 million on technical assistance brought the total since 1951 to £7·06 million, and the 565 students in the United Kingdom undergoing training on June 30, 1961, brought the total of Asian students who have received instruction in the United Kingdom under the Plan to 3,892, and total expenditure for this purpose to £3·12 million. The 42 experts provided during the year brought the total to 427, and the £235,988 provided for equipment for training and research purposes brought the total under this head to £2·01 million. Capital aid expenditure during the year amounted to £34·76 million, bringing the grand total under the Plan to £175·72 million, with outstanding commitments at June 30, 1961, of £82·55 million.

PLANT TISSUE AND ORGAN CULTURE

A SYMPOSIUM on the above subject was organized under the joint auspices of the University of Delhi and of the South Asia Science Co-operation Office of Unesco, which is also at Delhi. These arrangements were made by Prof. P. Maheshwari on behalf of the University of Delhi and by Dr. J. Swarbrick on behalf of Unesco. The 38 active participants in the symposium are greatly indebted to its organizers for the opportunity so presented to discuss various aspects of this interesting and rapidly developing field of work, which was covered in 36 different papers presented to the symposium. These papers will be made more widely available in a symposium volume which is to be printed as a separate issue of the journal *Phytomorphology*.

Seven foreign delegates were able to participate in the conference under the arrangements made by Unesco. These delegates were: Dr. J. P. Nitsch (from Laboratoire de Phytotron, Gif-sur-Yvette), Prof. J. Reinert (Pflanzenphysiologisches Institut der Freien Universität, Berlin-Dahlem); Prof. H. E. Street (Department of Botany, University College of Swansea), Prof. F. C. Steward (Cornell University, Ithaca, New York), Dr. A. N. Rao (University of Malaya), Prof. B. L. T. de Silva (University of Colombo), Dr. Tun (University of Mandalay). The remainder of the delegates to the symposium were from different parts of India.

Four of the foreign delegates (Dr. Nitsch, Profs. Reinert, Steward and Street) delivered informative general lectures under the following titles: "The *in vitro* Culture of Flowers and Fruits" (Dr. J. P. Nitsch); "The Experimental Modification of Growth and Differentiation in Plant Tissue Cultures" (Prof. J. Reinert); "Carrots and Coconuts: Some Investigations on Growth" (Prof. F. C. Steward); "Nutritional Problems Raised by Work with Root Cultures" and "Studies on the Hormonal Control of Root Growth" (Prof. H. E. Street).

In addition, these delegates delivered other papers on more specialized subjects such as: carbohydrate nutrition of excised tomato roots (Prof. H. E. Street); naturally occurring growth substances in relation to the growth of tissue cultures (Dr. J. P. Nitsch); and totipotency and variation in cultured plant cells (Prof. F. C. Steward). In this way these four foreign delegates presented to the symposium a broad picture of work in their respective fields and laboratories. This was further supplemented by two films in sound and colour, which had previously been recorded by Prof. F. C. Steward, and were shown under titles of "The Requirements for Growth in Plants" and "Growth and Development of Plants".

The remaining papers fell into four main groups: (1) nine papers dealt with the culture of reproductive organs such as the nucellus (as in citrus), embryos, ovules, ovaries, flowers or pieces of inflorescence; (2) four papers on the culture of cryptogams, particularly fern gametophytes, the thalli of *Marchantia*, and on the culture of a moss (*Physcomitrium coorgense*); (3) four papers on the culture, mostly the technique of culture, of grown gall tumour tissue from the hollyhock (*Althaea rosea*); (4) four papers dealing with aspects of morphogenesis in tissue cultures of horseradish (*Armoracia lapathifolia*), of carrot root (*Daucus carota*), in orchid seedlings, and in *Bryophyllum*.

The conference drew heavily on the wealth of experimental morphological material which was available in the Department of Botany at Delhi, through the work of students working largely under the direction of Prof. P. Maheshwari and Dr. B. M. Johri as well as of other members of the Delhi staff. This Department, already well known for its contributions to plant morphology, has turned increasingly in recent years to an experimental approach to morphological problems. The visitors to the conference were impressed with the range of interesting plant material under investigation by these means, especially the examples of the culture of nucellus, ovules, ovaries, etc., and of other parts of the reproductive system. It is a healthy sign for plant morphology, and one from which physiology will also profit, that those already well trained in morphology are now bringing their skills to bear on the culture of selected and interesting plant parts. The published volume that will recount these various investigations may thus be anticipated as one which will significantly advance knowledge in this field. The hope also is that the conference will have stimulated interest in this subject in South-East Asia, even as it furnished the foreign delegates with a valued opportunity to see what is going on in India.

In fact, at the end of the Delhi symposium, Dr. Nitsch and Profs. Reinert, Steward, and Street went to the Indian Science Congress, held at Cuttack, where they were again received as foreign delegates and guests of the Congress. Dr. Nitsch and Profs. Street and Steward delivered special lectures to the Indian Science Congress on topics similar to those presented to the Delhi symposium; Prof. Steward also addressed the annual meeting of the Indian Society of Biological Chemists. on the "Soluble Nitrogen Compounds of Plants", and Profs. Street and Steward participated with the Indian Society of Plant Physiologists in a meeting specially devoted to honouring Prof. F. G. Gregory, whose recent death was especially regretted in India where there are so many plant physiologists who were trained by him.

The foreign delegates especially are deeply grateful to the University of Delhi, to Unesco, and to the organizers of the Indian Science Congress for the opportunity to present an account of their own work and also to understand more about the range of experimental botanical work in progress in the various centres which they were able to visit. This left an impression of experimental plant morphology as a thriving branch of experimental science, which poses unique problems of growth and development for botanists to solve. In doing this work, classically trained morphologists and biochemically trained physiologists can now usefully combine forces and so benefit their respective disciplines.

TEXTILE RESEARCH AND COLOUR CHEMISTRY AT LEEDS

THE eighty-fifth and eighty-sixth reports of the Advisory Committee on Textile Industries and Colour Chemistry and Dyeing in the University of Leeds to the Worshipful Company of Clothworkers, covering the sessions 1958–59 and 1959–60, record considerable progress*. In the Department of Textile Industries the number of students remained about 400, but in 1958–59 extra-mural activities were an outstanding feature. In textile physics considerable progress was made in electron microscopic studies of various fibres. The uranyl group has been found to give selective staining of the endo-cuticle, and it has also been shown that two intercellular layers of the cell-membrane complex are attacked by keratinolytic reagents and enzymes. The structural changes brought out by variations in the conditions under which filaments of polyacrylonitrile are spun have also been studied.

In textile chemistry, cross-linking and polymerization reactions continued to receive much attention. The physical properties of wool fibres (elastic modulus, swelling ratio) have been correlated with theoretical predictions. It has also been shown that an oxidized and alkali-treated wool fibre shows reversible spontaneous contraction and extension as the *p*H of an ambient aqueous solution is altered, the thermodynamic and X-ray diffraction results corresponding closely to those observed with muscle preparations. New methods of forming anchored and unanchored polymers on and in wool fibres have been evolved, and promising results have been obtained with insoluble organic pigments in the low-temperature, solvent-assisted method of dyeing. The constitution of suint has been established as essentially a polymerized dihydroxyphenol carrying a long-chain acid which can form peptide links with amino-compounds. The heat, free energy and entropy of sorption of methacrylic acid from aqueous solution by nylon have been determined, and the polymerization of methacrylic acid in nylon and the properties of nylon fabrics containing this polymer are being examined. The thermodynamic functions of β-keratose fibres are being examined and also the setting properties of wool, and the plasticity of wool has been related inversely to the sulphur content of the β-keratose obtained from the oxidized fibres. The principles underlying the use of tetrakis (hydroxymethyl) phosphonium chloride in flame-proofing wool have been examined, and it has been found that presence of this substance enhances the ability of fibres to take a set in aqueous media.

* Reports to the Worshipful Company of Clothworkers of the City of London of the Advisory Committee on the Departments of Textile Industries and Colour Chemistry and Dyeing in the University of Leeds. Session 1958–59: Pp. 50; Session 1959–60. Pp. 52. (Leeds: The University.)

In the Department of Colour Chemistry and Dyeing there were 48 undergraduate students in the eightieth (1958–59) and 45 in the eighty-first (1959–60) session, with 17 and 23, respectively, working for higher degrees. A study of the influence of the acetyl value of acetate rayon on the rate of dyeing and affinity of disperse dyes was completed. Work continued on the kinetic and thermodynamic aspects of the dyeing of acetate rayon with sulphated dyes and on the influence of the chemical constitution of non-ionic azo dyes on their affinity for cellulose. Other work has been concerned with the effect of benzyl alcohol and *n*-butyl alcohol on the absorption by wool of dyes containing metal and the chemistry of ketones related to *meso*benzanthrone, particularly their behaviour towards substituting agents and their ability to undergo self-union in alkaline media with formation of vat dyes. An investigation of the status of sulphinic acids as substituting agents yielded some interesting and potentially useful sulphones and some new reactions, and provided an explanation of the course of several applications of sulphinic acids in organic chemistry. Work was completed on derivatives of 2-methylanthraquinone and 2-alkylquinizarins and the influence of the chemical constitution of non-ionic azo dyes on their affinity for cellulose. Lists of publications during the year are included in both reports.

THE BRITISH LEATHER MANUFACTURERS' RESEARCH ASSOCIATION

The annual report of the British Leather Manufacturers' Research Association for the year October 1960–September 1961*, includes the reports of the Council and of the Director of Research, the latter including a list of publications, together with details of membership of the Council, its committees and of staff. Renewed attention was given to the problem of finding new outlets for leather and emphasis was placed in a report to the Council on the overwhelming importance of using the raw hides and skins to the best advantage.

The Director's report outlines the programme of research for 1961–62 and notes some features of the current year's work. In background research, work on the composition of skin proteins centred on the separation of collagenous and non-collagenous protein in acetic acid extracts of calf-skin. Investigations of the mechanical and elastic properties of collagen and leather have been extended to combination-tanned fibres, both semichrome and chrome re-tan. In studying the deterioration of leather by heat, moisture and perspiration it has been shown that exposure to dry heat or to high humidities at normal temperatures causes little deterioration and that it is the combined action of heat and moisture which is deleterious, involving breakdown of polypeptide chains both by hydrolysis and an oxidative process involving loss of amino-acids.

Experiments in which sheep-skins were deliberately allowed to stale before using have shown that while staling reduced the quality of the skins, as judged by thinness, pits and holes and also the strength of the leather, it did not appear to lower rot-resistance. Examination of the effect of adding antiseptics to the salt used for curing sheep-skins indicated that processes within the control of the fellmonger or tanner have at least as big an effect. Progress in reducing the cost of unhairing by enzymes is reported through the demonstration that the enzyme liquor can be re-used several times. It has also been found that salt concentrations of 10 per cent or more reduce enzyme activity in de-woolling sheep-skins and a 2 per cent solution of enzyme is just as effective as a 20 per cent solution.

Other work has been concerned with control of the thickness of vegetable-tanned sole leather, vegetable tan sludges, laminated leathers and solvent-assisted dyeing, in which a technique was developed for topping suèdes by spraying by emulsifying in water a solution of the pigment dyestuff in benzyl alcohol. More recently, anionic dyestuffs have been dissolved in a single-phase solvent system of water, isopropyl-alcohol and benzyl alcohol and sprayed direct on to the leather. Work has been started on new impregnating finishes for upper leather and considerable progress made in waterproofing chrome upper leather with silicones. The outstanding problem remaining is to improve the retention of silicones by the leather over long periods of use.

NEW DIRECTIONS IN PETROLEUM EXPLORATION, PRODUCTION AND TRANSPORTATION

Writing in the November–December 1961 issue of the *Battelle Technical Review* published by the Battelle Memorial Institute, Columbus, Ohio, Dr. Frank C. Croxton propounds some novel, if not revolutionary, ideas for explorations of oil-pools, techniques for crude-oil production and transportation.

In the field of exploration location of future oil deposits envisages extensive use of gas surveys, microbiological indicators, radio-geochemical methods and advanced electronic instruments. The aim is development and use of geophysical methods of greater sensitivity and portability, thus utilizing more direct methods of oil-finding, especially in "vast new areas which are conceivably as rich as the rest of the world in oil reserves". In the realm of production, conventional drilling operations may well be superseded by processes designed to eliminate altogether the rig as we know it to-day; in this direction the author relies on the rapidly advancing knowledge of more efficient application of energy, for example, effects of high temperature, explosives, sound and supersonics. "Production research of the future will, therefore, give much attention to faster and more economical ways of making, in rock, holes a few inches in diameter, many thousands of feet long, and aimed with precision." This ideal implies removal of torsional and tensile stresses from the drill-string, replacing drill-heads by electrical currents, use of plasma techniques, and even underground nuclear explosions.

Thermal drive, that is, heating the underground crude-oil deposit, is forecast as a secondary recovery procedure, since at elevated temperatures viscosity would be reduced and thereby flow to wells accelerated. As a corollary to this the possibility of attaining cracking temperatures, "*in situ* vis-breaking operation of the crude", is seriously considered.

Two noteworthy advances in petroleum transportation are the flexible oil barge and the flexible pipeline. The former, made of nylon-reinforced rubber, is towed practically submerged to its destination, thereafter collapsed into a comparatively small package and shipped back to point of origin. Flexible pipe-line, of proved value in submarine transportation of oil during the Second World War and since, is destined to be of far greater importance in this connexion in the future. "It has not been given to previous generations to see an area of technology born, develop to maturity, and then experience a substantial evolution, all during a human lifetime." Such has indeed happened in the petroleum industry, and because of this Dr. Croxton's speculations in this paper cannot be dismissed lightly.

SYNTHESIS OF PROTEIN AND RIBOSOMES BY BACTERIA

By Dr. S. DAGLEY, Dr. A. E. WHITE and Dr. D. G. WILD
Department of Biochemistry, University of Leeds
AND
Dr. J. SYKES
Department of Biochemistry, University of Sheffield

THE antibiotic chloromycetin (chloramphenicol) inhibits protein synthesis in bacteria but allows synthesis of ribonucleic acid (RNA) to continue[1]. Although there is evidence for a type of RNA termed 'messenger'[2,3] which is rapidly synthesized and degraded in *Escherichia coli*, most bacterial RNA exists as ribosomes which are particles containing protein and stable RNA. This 'normal RNA' differs from that accumulated during chloromycetin inhibition: the latter may be rapidly degraded by the cells during a phase of recovery from the antibiotic and some of the bases or nucleosides may pass from the cells into the surrounding medium from whence they are reabsorbed when growth resumes[4].

This contrast in stability has given rise to the view that 'chloromycetin RNA' is abnormal or non-functional despite the fact that its base composition is the same as that of normal RNA (ref. 5). It may be noted, however, that the kinetics of degradation are not those to be expected for a detoxication process by which useless or harmful material is ejected: that is, degradation does not begin some time after the new material has accumulated; instead, synthesis and degradation proceed simultaneously with the rate of the former initially greater, so that 'chloromycetin RNA' is observed in radiotracer experiments to be 'turning over' during the whole period of its accumulation[5]. There is, in fact, no direct experimental evidence that this RNA causes protein synthesis to cease; on the other hand, it has been shown that chloromycetin itself inhibits biochemical reactions preceding peptide-bond synthesis, namely, those concerned with transfer of amino-acids from 'soluble RNA' to ribosomes[6].

Our results, and those of other workers, are readily interpreted on the view that: (1) most of the RNA synthesized by bacteria is labile unless it combines with protein; (2) 'chloromycetin RNA' is exceptional only in so far as it occurs in particles with a lower ratio of protein : RNA than that normally found, one of the effects of the antibiotic being to favour their stabilization. Such particles may normally exist as precursors of ribosomes.

When the cell synthesizes protein at the normal rate only a few of them may exist at any given time since they would be removed by the completion of stable ribosome structures; and when protein synthesis is suppressed by chloromycetin they would also be rapidly degraded by enzymes unless combination with the antibiotic, in addition to combination with protein, could reduce the rate of breakdown. Horowitz, Lombard and Chargaff[5] found that the RNA accumulating early in chloromycetin treatment was more stable than that accumulating later: thus, a factor opposing breakdown, probably protein, appears to have been less readily available the longer protein synthesis was inhibited. In agreement with this view it has been shown that 'chloromycetin RNA' occurs in particles which have a lower ratio of protein : RNA than 50*S* ribosomes and give rise to additional peaks in schlieren diagrams at 14–18*S* [7–9]. We find that extracts of puromycin-treated cells also show additional peaks sedimenting at this speed on examination in the ultracentrifuge. Now puromycin appears to inhibit the same steps in protein synthesis as chloromycetin[10], but in contrast the RNA which accumulates is stable[11]. Accordingly, the argument that 'chloromycetin RNA' is abnormal because it is labile is greatly weakened: the ribonucleoprotein (RNP) particles which accumulate during inhibition by puromycin are similar physically to those from chloromycetin treatment, but they contain stable RNA. It is simpler to suggest that puromycin stabil-

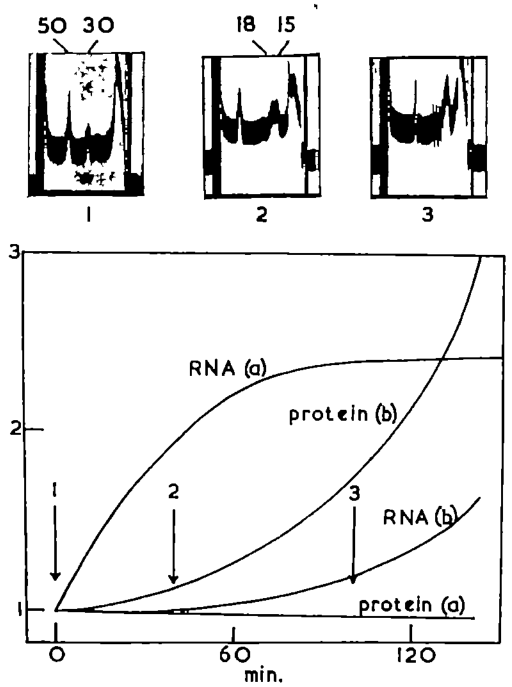

Fig. 1. Action of puromycin on *E coli* Bacteria were incubated at 37° with 0·5 mgm. of puromycin/ml. of growth medium Changes in amounts of intracellular RNA and protein are expressed as multiples of the initial values: curves (*a*). Cell extracts, each containing 10 mgm. of protein/ml., were prepared at times shown by arrows, and the corresponding Schlieren diagrams are given above the graphs. Sedimentation at 187,000*g* is to the left, and photographs were taken 16 min. after reaching full speed. Each leading peak is due to 50*S* ribosomes and in (1) this peak and that for 30*S* ribosomes are numbered. In (2), peaks for 'puromycin RNA' are numbered 18 and 15; in (3), some convection has occurred on account of the high concentration of RNA. In a second experiment, bacteria were incubated for 100 min. with puromycin as above and then washed and incubated in growth medium without antibiotic. Increases in intracellular RNA and protein are expressed as multiples of initial values on resuspension curves (*b*)

izes ribosome precursors more effectively than chloromycetin for reasons that will be discussed.

The strain of *E. coli* used in previous investigations with chloromycetin[8,9] was collected from a similar growth medium, and the cells were re-suspended in an equal volume of fresh medium at 37° C. containing 0·5 mgm. of puromycin/ml. This concentration, which gave 80 per cent inhibition of growth measured by turbidity, is greater than that used in experiments with chloromycetin since the strain is more sensitive to the latter than to puromycin. At various times during the incubation, cells were centrifuged, disrupted[12] and extracted with 0·015 *M* phosphate buffer, *p*H 7, and the clarified cell extracts were examined in the ultracentrifuge. There was no net synthesis of protein, but the amount of RNA increased by 250 per cent during incubation with puromycin (Fig. 1); also, ultracentrifuge patterns showed additional peaks at 15*S* and 18*S*, in the same region as those observed for chloromycetin.

As seen in Fig. 1, when puromycin-treated cells were washed and incubated in growth medium without antibiotic there was a gradual resumption of protein synthesis but little increase in RNA for 120 min. During this phase of metabolic recovery the 15–18*S* peaks were gradually lost from Schlieren diagrams, and there was a reversion to the characteristic pattern for untreated cells. These changes were much slower than those found for chloromycetin-treated cells when 30 min. after release from the antibiotic, the 14–18*S* peaks of 'chloromycetin RNP' disappeared and were replaced by a large single peak due to 30*S* ribosomes. The slower resumption of protein synthesis after puromycin treatment and the stability of the additional RNA may both be due to stronger binding of puromycin to ribosomal RNP. The structural formula of the antibiotic resembles that of aminoacyl RNA[13], and ribosomes are irreversibly poisoned for *in vitro* experiments concerned with protein synthesis[10]. If puromycin is strongly bound to sites it may be displaced by metabolites only on resumption of protein synthesis and this would therefore be a gradually accelerating process, as in Fig. 1. Incorporation of 'additional RNA' into ribosomes from their precursors would also be slow.

Borek and Ryan[14] showed that a mutant of *E. coli* requiring methionine for growth continued to synthesize RNA when protein synthesis ceased due to lack of methionine. Dr. W. Hayes kindly provided us with a similar strain of *E. coli* which showed this effect. This mutant synthesized little or no protein when cells were suspended in a methionine-free medium and after 180 min., synthesis of additional RNA also ceased. Cell-free extracts made at this time showed additional peaks in the same region of the ultracentrifuge pattern as those arising from the action of chloromycetin and puromycin, namely, at 14*S* and 16*S* (Fig. 2). When methionine was added and protein synthesis resumed, these peaks diminished and there was a simultaneous increase in area of the peak due to 50*S* ribosomes: these changes took place over a time-interval for which the increase in turbidity corresponded to less than one-third of a generation. The peaks at 14*S* and 16*S* may thus be due to ribosome precursors stabilized by protein which becomes available by 'turnover' of pre-existing material, known to occur in starved bacteria[15]; how-

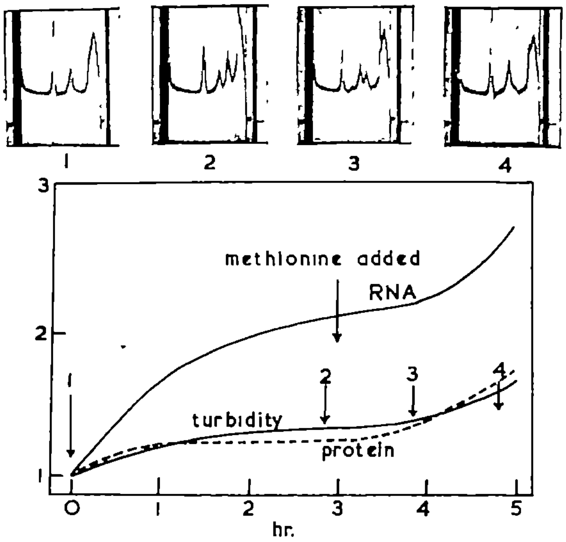

Fig. 2. Ribonucleic acid content of a methionine-requiring mutant of *E. coli*. A fully grown culture was collected and the bacteria resuspended in glucose and mineral salts medium lacking methionine. Curves show the increases in turbidity of the culture and intracellular concentrations of RNA and protein, all expressed as multiples of initial values. *dl*-Methionine (130 μgm /ml.) was added after 3 hr. Cell extracts were prepared at times indicated by arrows and the corresponding Schlieren diagrams, which are shown above the graphs, differ in appearance from those of Fig. 1 because a phase-plate was used. Sedimentation at 187,000*g* is to the left and photographs were at 16 min. The leading peaks in every photograph are for 50*S* and 30*S* ribosomes: the additional third peak which appears in photographs (2) and (3) resolved into two peaks (14*S* and 16*S*) on further sedimentation

ever, before it can be finally accepted, this view must be tested by experiments using radioisotopes in order to decide whether there is a direct incorporation of 14–18*S* RNA into 50*S* ribosomes. The additional RNP of the mutant resembles 'puromycin RNP' in metabolic stability, and both resemble 'chloromycetin RNP' in being broken down by short exposures to sonic vibrations which leave 50*S* ribosomes unaffected.

The purine analogue 8-azaguanine resembles chloromycetin in its action on *Bacillus cereus* because the synthesis of cytoplasmic protein is suppressed in both cases, but not the synthesis of RNA or cell-wall material[16]. 'Azaguanine RNA' is certainly abnormal since the analogue is incorporated into polynucleotide chains[17], and it may be argued from the similarity in action of the two inhibitors that 'chloromycetin RNA' is also abnormal. However, experiments like those of Fig. 1 were performed for *B. cereus* treated with 8-azaguanine and for *E. coli* with 8-azaadenine: protein synthesis was inhibited and RNA accumulated, but there were no additional peaks in ultracentrifuge patterns such as those shown for chloromycetin and puromycin. In this respect, therefore, the antibiotics differ from the purine analogues: 'azaguanine RNA' evidently exists as much smaller units than 'chloromycetin RNP'. Mandel and Markham[18] found that polynucleotides built during inhibition with azaguanine had relatively short chains; while experiments of Aronson and Spiegelman[19] suggested that 'chloromycetin RNA' occurs in large units, probably precursors of ribosomes, which are not degraded when the bacteria were supplied with amino-acids but were converted directly into ribosomes. Since these important experiments were rather briefly reported, we have confirmed that when ^{14}C-uracil is incorporated into 'chloromycetin RNA' it leaves the cells when they are washed and then incubated with mineral salts medium, but it remains inside them if peptone is present during the phase of recovery.

Very recently a complete account of the work of Aronson and Spiegelman has appeared[20] which supports the view that 'chloromycetin RNA' is a normal intermediate in the fabrication of ribonucleoprotein. They present a formal scheme in which stable free RNA undergoes conversion to an unstable form before RNP is synthesized and suggest that the action of chloromycetin is to block this conversion.

Several features of our work have a wider interest than the elucidation of antibiotic action. First, when peaks due to 'chloromycetin RNP' are lost from ultracentrifuge patterns their place is taken by a single peak at 30*S*: there is little or no change in area of the 50*S* peak at this time. The reverse is true for the 'mutant RNP': a precursor-product relationship seems to exist between 14–16*S* material and 50*S* ribosomes but not with 30*S* ribosomes. Although the two types or ribosomes may have common precursors at an early stage in synthesis, they thus appear to be formed from them by separate routes. Secondly, 'mutant RNP' sediments at 14*S* and 16*S*; it is much more sensitive to ribonuclease than are 50*S* ribosomes; and when the Mg^{++} ion concentration of extracts is raised to 10^{-2} *M* so that 70*S* ribosomes are formed, the 14*S* and 16*S* peaks are lost and a larger and broader peak than in normal extracts appears in the 30*S* region of the pattern. 'Chloromycetin RNP' also sediments at 30*S* when the Mg^{++} ion concentration is raised[7,9]. A similar set of properties is claimed for the 'messenger RNA' of uninfected bacteria[3]; and since ribosome precursors may also incorporate radiotracers very rapidly it is clearly impossible to distinguish between the two forms of RNA by sedimentation and tracer studies alone. Thirdly, the practice of preparing extracts in 10^{-2} *M* magnesium acetate solution for ultracentrifuge analysis has been criticized in a previous communication[21]. Had we used this solvent, the changes we have described would not have been observed since most of the RNP would have sedimented at 30*S* or at higher speeds.

We thank the Medical Research Council for financial assistance.

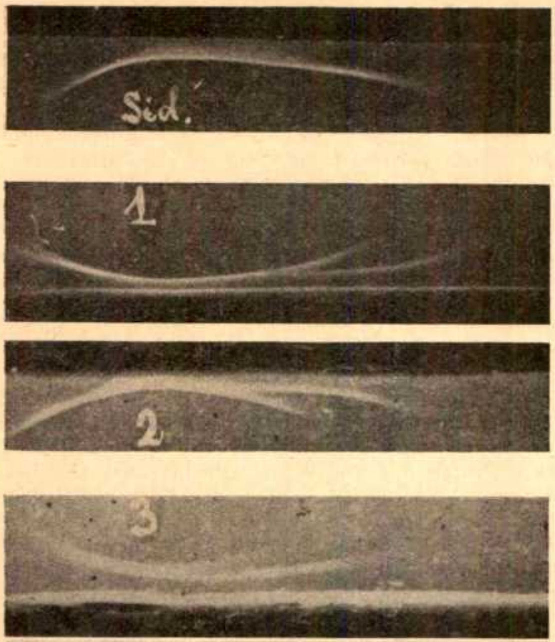
IMMUNOCHEMICAL STUDIES ON HUMAN SIDEROPHILIN

Enzymatic Splitting of the Antigenic Structure of Siderophilin

PURIFIED human siderophilin was submitted to enzymatic proteolysis in order to obtain fragments carrying parts of its antigenic structure[1,2]. (The starting material was Cohn fraction IV, 4, which was obtained through the courtesy of Dr. K. Walton, Department of Experimental Pathology, the Medical School, Birmingham; the purification was achieved by 'Rivanol' precipitation followed by DEAE chromatography in acetate buffer *p*H 6, 0·01 *M* and *p*H 5·4, 0·02 *M*. The material obtained showed traces of γ-globulin impurity when tested by immunoelectrophoresis with a powerful anti-whole human serum antiserum. For our study, we had an anti-siderophilin serum which gave no precipitation with other constituents of human serum obtained through the courtesy of Dr. J. F. Soothill, Department of Experimental Pathology, the Medical School, Birm-



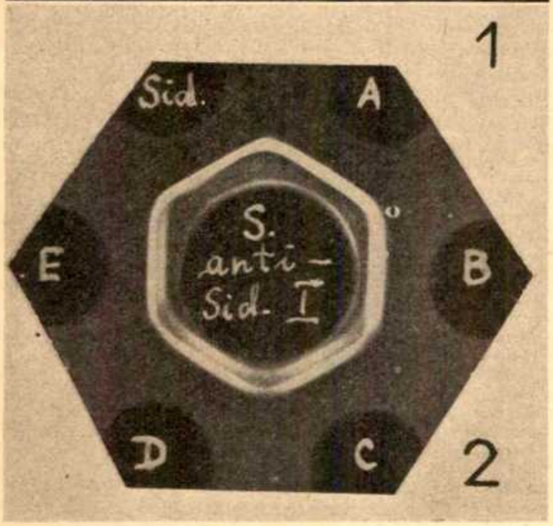


Fig. 1. The immunoelectrophoretic pattern of the control siderophilin and three degraded samples (enzyme: chymotrypsin; 45·64 and 75 per cent of material non-precipitating with 5 per cent trichloroacetic acid)

Fig. 2. Comparison of the control siderophilin, one trypsin-degraded (*A*) and two chymotrypsin-degraded samples of plasma siderophilin (*B*, *C*); two chymotrypsin-degraded samples of urinary siderophilin (*D*, *E*)

ingham. The siderophilin preparation used was saturated with iron and was pink-coloured—other preparations, containing a little albumin, were yellow-red.)

The enzymes chosen for the proteolysis were papain, trypsin and chymotrypsin, all acting in neutral or alkaline *p*H in order to avoid the splitting of the iron occurring at acid *p*H.

The papain digestion did not produce a visible change of immunological properties. Trypsin and chymotrypsin were used at *p*H 8·1 either in borate or phosphate buffer or without buffer. The amounts of enzymes used varied between 1 and 10 per cent for 1–5 days at 37° C.

The observed changes were less in borate buffer and the best conditions were without buffer.

The tryptic and chymotryptic digestions result in the splitting of a considerable amount of material: after dialysis the remaining protein (as measured by biuret reagent) is about 25 per cent of the original material. After chymotryptic digestion the protein loses its colour; for example, when comparing three degraded samples, 1 (45·6 per cent of material non-precipitating with trichloroacetic acid at 5 per cent), 2 (64 per cent) and 3 (75 per cent), the first was pink-coloured, the second very pale and the third colourless (all three were compared at the same concentration of biuret-reacting material). Tryptic digestion did not produce such changes. It was impossible to fix iron on those colourless samples.

The sedimentation constants of the first two samples were very close to that of the control siderophilin (4·68 and 4·18); the third sample showed 2·37, but the concentration of the material was very low (0·1 per cent biuret-reacting material).

The immunochemical changes are seen in Figs. 1 and 2. By immunoelectrophoretic analysis in barbiturate buffer, *p*H 8·2, two lines are shown by the degraded samples; they seem not to be separate lines, but they may be superimposed for the first two samples; the third gives two lines of very similar electrophoretic mobility. By double diffusion in agar, two separate lines can be obtained when the most degraded samples are tested. The patterns obtained vary with the antiserum used, which means that the proportions of different antibodies may be widely different.

Thus the antigenic structure of siderophilin is split by trypsin and chymotrypsin and the digestion results in two separately precipitating components.

A mixture of a series of degraded samples was separated by DEAE cellulose chromatography into four fractions: with acetate buffer *p*H 6, molarity 0·01, the first fraction was a pink-coloured material which showed no splitting when tested by immunoelectrophoresis and resembled the original siderophilin.

The second fraction eluted with the same buffer was very slightly coloured and showed no definite splitting by immunoelectrophoretic analysis.

The third fraction was eluted with a buffer of *p*H 5·4 and molarity 0·02; it was coloured, and by immunoelectrophoresis showed a pattern of two lines separated at the anodic extremity. Washing the column with the same buffer removed a final product which was colourless (after concentration it was greenish) and showed two separate lines by immunoelectrophoresis.

The sedimentation constants were 5·14 and 3·29 (50 per cent of each constituent) for the third fraction and 4·38 (100 per cent) for the last.

A preparation of urinary siderophilin from patients with proteinuria (obtained through the courtesy of Dr. J. Hardwicke, Department of Experimental Pathology, the Medical School, Birmingham) was submitted to proteolysis in the same conditions. Immunoelectrophoresis showed splitting of the line, while, by double diffusion in agar, comparison of the degraded samples of plasma and urinary siderophilins the analogous lines fused (Fig. 2). Thus, with respect to the anti-plasma siderophilin serum used, both degraded products seem identical.

Cross-reactions of Human and Monkey Siderophilin

When tested by immunoelectrophoresis chimpanzee siderophilin has not the same mobility as human, rhesus or baboon siderophilins (Fig. 1). (The antigens used in this work were: for the human siderophilin either the purified preparation[1] or the whole serum, and for monkeys the whole individual sera: 6 chimpanzee sera, 6 rhesus sera and 2 baboon sera. The antisera were three pools of sera from rabbits immunized with a purified siderophilin preparation which were obtained through the courtesy of Dr. J. F. Soothill.)

By double diffusion in agar with the antiserum I (the same as used previously[1]) no cross-reaction (spur formation) was observed between human and any monkey siderophilins. With sera II or III, spurs are seen between human or chimpanzee siderophilin lines and rhesus or baboon siderophilin lines.

Fig. 2. Reactions of horse, chimpanzee, baboon, rhesus, pig and human siderophilins with the anti-human siderophilin serum I

Fig. 3. Reactions of human, chimpanzee, rhesus, baboon and horse siderophilins with anti-human siderophilin sera I, II and III

Fig. 4. Immunoelectrophoretic pattern of a chymotrypsin degraded sample of human siderophilin revealed by anti-human siderophilin serum II: unabsorbed and absorbed by baboon siderophilin

The lines of human and chimpanzee siderophilins and of baboon and rhesus siderophilins fuse completely, thus showing their immunological identity with respect to those two antisera (Figs. 2 and 3).

None of the antisera tested reacts with horse, pig or goat siderophilins (Figs. 2 and 3).

When comparing several spurs formed by those cross-reacting systems it seems that the difference between chimpanzee and rhesus is greater than between human and rhesus siderophilins.

All observed spurs are shorter than those formed, for example, by horse serum albumin and bovine serum albumin with anti-horse serum albumin serum, or hen and duck ovalbumins with anti-hen ovalbumin, and they are often very weak.

Since the length of a spur seems independent of the density of the line it means that the length of the spur is probably related to the number of determinant groups in the two antigens being compared using a particular antiserum[2], and the density of the spur line reflects the quantitative relationship between the amount of antibody reacting only with the homologous antigen and antibody reacting with both homologous and heterologous antigens.

It was not possible to absorb all antibodies reacting with the homologous antigen in sera II and III with the heterologous antigen.

When the antiserum II or III absorbed by rhesus or baboon serum is used for the immunoelectrophoresis of a digested sample of human siderophilin which gives two lines with the unabsorbed serum I only one line can be seen (Fig. 4). When the degraded siderophilin gives only a line split at one extremity with the unabsorbed antiserum, there is a single line with the absorbed antiserum.

These facts resemble the observation on the reaction of papain-degraded human γ-globulins with the corresponding antiserum absorbed by rhesus γ-globulin[3], but they differ from the observation of chymotrypsin-degraded hen ovalbumin with the corresponding antiserum absorbed by duck ovalbumin[2].

When the same sort of experiment is performed using antiserum I which does not give any spur with monkey siderophilins, absorption by those heterologous antigens is capable of removing all antibodies precipitating with the homologous antigen, but more heterologous antigen is required to remove antibodies producing one line than the other.

Thus it seems that the antibodies present in antisera II and III which react only with the homologous antigen are related to antibodies precipitating with one of the components of digested human siderophilin while the antibodies precipitating with the other component are related to antibodies precipitating with both homologous and heterologous antigens.

I thank Prof. J. R. Squire and P. G. H. Gell and the staff of the Department of Experimental Pathology, the Medical School, Birmingham, for their hospitality during my stay in that laboratory.

SEPARATION OF AMINO-ACIDS BY CIRCULAR PAPER CHROMATOGRAPHY

By Dr. D. L. H. ROBINSON and Dr. G. A. T. TARGETT

Bilharzia Research Unit of the Medical Research Council, Winches Farm, Hatfield Road, St. Albans

CIRCULAR paper chromatography is said to have advantages over other methods of separating mixtures of amino-acids. The techniques of Krishnamurthy and Swaminathan[1] gave striking results but they have not come into general use. In this communication we summarize a practical method of separating amino-acid mixtures by circular paper chromatography in a modified Kawerau apparatus.

The starting point was Krishnamurthy's method which separated the 16 amino-acids of casein on circular paper 28 cm. in diameter. The papers were supported on a glass stand and the wick was a piece of filter paper 2 × 3 cm., rolled and cut at one end to form a brush. The whole was covered by a circular glass trough 30 cm. in diameter. Five solvents were used: (*a*) phenol/butanol/acetic acid/water 20 : 20 : 8 : 40; (*b*) phenol saturated with *p*H 12·0 buffer; (*c*) *m*-cresol saturated with *p*H 8·4 buffer; (*d*) 1-butanol/acetic acid/water, 40 : 10 : 50; (*e*) benzyl alcohol/tertiary amyl alcohol/water, 50 : 50 : 100. The papers were multiple developed.

We experienced considerable difficulty in repeating Krishnamurthy's method in a Kawerau apparatus. The method which follows proved satisfactory for the study of amino-acids in schistosomes and their hosts.

Whatman No. 1, 26·5 cm., slotted (5 section) circular papers were used, buffered when necessary by running them in a Kawerau dish until fully saturated. The solvents, prepared as described here, were shaken vigorously for 15–20 min. and allowed to stand for 2–6 days before use. Amino-acid samples were streaked on the paper at a distance of 1·5 cm. from the centre. After multiple development, the chromatograms were dipped in 0·25 per cent ninhydrin in acetone to detect the amino-acids.

Initially, the aim was to obtain good separations in standard 26-cm. Kawerau dishes, but the dishes were too small. When the solvent front was kept within the border of the dish the separation was poor, but if the solvent were allowed to travel beyond the ground glass surfaces of the base and lid, its movement was irregular and the amino-acid bands on the chromatograms were often diffuse and uneven. Evaporation of volatile solvents, such as benzyl alcohol/tertiary amyl alcohol/water, occurred at the edge of the paper and prevented identification of the outer bands.

The following modification was made to allow longer development. The Kawerau dish, without the lid, was placed in a pneumatic trough, 30 cm. in diameter by 12 cm. deep. Four pieces of fine drawn capillary tubing were placed across the Kawerau dish to support the paper. The solvent was placed in the outer dish as well as in the Kawerau base to ensure a saturated atmosphere. After equilibration at 70° F. the paper was inserted, the lid of the trough replaced and development started.

Methods for Different Solvents

(1) *Phenol/1-butanol/acetic acid/water*. 20 vol. of hot phenol were stirred into a mixture of 20 vol. of 1-butanol, 8 vol. of glacial acetic acid and 40 vol. of water. After shaking for 20 min. and standing for three days, the top layer was used as a solvent. Papers used with this solvent were buffered at *p*H 2·0 with potassium chloride/hydrochloric acid buffer of McFarren[2] before being developed three times for 5½–6½ hr. Development was always stopped within 1 hr. from the time the solvent front reached the edge of the paper.

(2) *Phenol p*H 12·0. An excess of sodium hydroxide/disodium hydrogen phosphate *p*H 12·0 buffer[2] was stirred into hot phenol, shaken and allowed to stand. The lower layer was used as a solvent with papers buffered at *p*H 12·0. Double development for 6–7 hr. gave satisfactory results.

(3) *Cresol p*H 8·4. Cresol (mixed isomers) was mixed up with an excess of boric acid/potassium

Table 1. CHROMATOGRAPHIC BANDS SEPARATED BY THE FIVE SOLVENTS

	Butanol–acetic acid–water	Phenol–butanol–acetic acid–water	Cresol	Phenol	Tert. amyl alcohol–benzyl alcohol

1, Our results; 2, results of Krishnamurthy and Swaminathan (ref. 1).

chloride/sodium hydroxide pH 8·4 buffer[2]. After shaking and standing, the bottom layer was used as a solvent. The papers, which were treated with the same buffer at pH 8·4, were developed three times for 9–10 hr.

(4) *Butanol/acetic acid/water*. This was prepared by adding 40 vol. of 1-butanol and 10 vol. of acetic acid to 50 vol. of water. The mixture was shaken and allowed to stand; the top layer was used as a solvent. Unbuffered papers were used and developed three times for 5–7 hr.

(5) *Tertiary amyl alcohol/benzyl alcohol/water*. 50 vol. of tertiary amyl alcohol and 50 vol. of benzyl alcohol were shaken with 100 vol. of water. After shaking and standing, the top layer was used as a solvent. Krishnamurthy *et al.*[1] say that this solvent can be used both with unbuffered paper or with paper buffered at pH 8·4; we have found that buffered papers give a better result. The papers were developed twice for 15–16 hr.

The results are shown in Tables 1 and 2. Table 1 lists the amino-acid bands formed by each solvent, arranged in order beginning with the outside band. Table 2 shows the amino-acids that are clearly separated by each solvent, and gives the results of Krishnamurthy for comparison.

As can be seen from Tables 1 and 2, R_F values have not been quoted. Although Krishnamurthy *et al.*[1] gave the relative distances travelled by the amino-acids, we found it more reliable to express the result as bands containing one or more amino-acids.

Chromatograms developed with tertiary amyl alcohol/benzyl alcohol/water gave a good deal of trouble, and we were unable to move the amino-acids to the edge of the paper. After three developments, the inner bands were separated, but at the expense of the outer, which became very diffuse. Since the main use of this solvent was to separate the outer bands, phenylalanine, isoleucine and leucine, the papers were only developed twice and gave good separation of these components.

MOLECULAR AND FINE STRUCTURE OF ALPHA-KERATIN

By D. J. JOHNSON and Dr. J. SIKORSKI

Textile Physics Laboratory, Department of Textile Industries, University of Leeds

IT has been difficult to reconcile the results obtained from the X-ray diffraction studies of metal-treated keratin fibres with the evidence revealed in the electron micrographs of their thin sections and fragmentation products[1,2]. Satisfactory, qualitative, agreement has long been evident between the transverse dimensions (d = 60–80 Å.) and packing of the individual ('cylindrical') microfibrils and the equatorial X-ray data. Yet, it has proved impossible to derive a quantitative expression which would account for the interference effects involved in such a system of cylinders, separated by distances of the same order of magnitude as their own dimensions[3]. The discrepancy between the values of the axial repeats: (1) 90 Å. observed directly in the intermicrofibrillar matrix of the longitudinal sections and fragmentation products of keratin, treated with silver nitrate, but not in the microfibrils themselves; (2) 25 Å. derived from the one-dimensional Patterson function, had to be resolved by our own suggestion that the metal atoms are deposited not only in the intermicrofibrillar matrix but also in the microfibrils themselves[2]. Indeed, Filshie and Rogers have found[4], in the paracortex of transverse sections of merino wool fibres, evidence of fine detail within the microfibrils which they regard as representing a system of nine peripheral sub-units (d = 20 Å.) with two similar subunits situated in the centre[5]. They stress a resemblance between this system and that found on a higher level of dimensions, in animal cilia[6] and bacterial flagella[7]. The sub-unit, designated as protofibril, was identified with the 3-strand rope (d = 20 Å.) of α-helices, which was shown, by Fourier transforms[8] and more recent work on optical transforms[5,9], to conform reasonably well with the X-ray data (there remains, however, the unexplained equatorial reflexion at 27 Å. and the low calculated density[8]).

We have obtained evidence of fine detail inside the microfibrils, in thin transverse sections of porcupine quill, reduced and treated only in osmium tetroxide (cf. ref. 10), but Filshie and Rogers found that a treatment with osmium tetroxide in bulk, followed by lead hydroxide after sectioning, was necessary to obtain adequate contrast in the electron micrographs of wool fibres[4]. We believe that it is not possible to consider the observed sub-units ($d = 20$ Å.) simply as end-on projections of unstained 3-strand ropes, surrounded by metal-containing inter- and intrafibrillar matrix, for the following reasons. First, because the orientation of the long α-helices ($d = 10$ Å.) in relation to the axis of the transverse sections, about 200–400 Å. in thickness, and tilting imposed by the morphology of cortical cells[11], the space-filling polyhedra[12], will affect the microscope image. Secondly, because of a periodicity of scattering sites along the loci of α-helices, revealed particularly well by an enhancement of the meridional reflexions of keratin containing one of the following elements, mercury[13,15,16], osmium[14,16], silver[15,16] or uranium[16], we would expect electron scattering of a type associated with some regularity of atomic arrays in a specimen, though much lower than in a crystal. Thirdly, the dimensions involved approach the resolving power of the microscope.

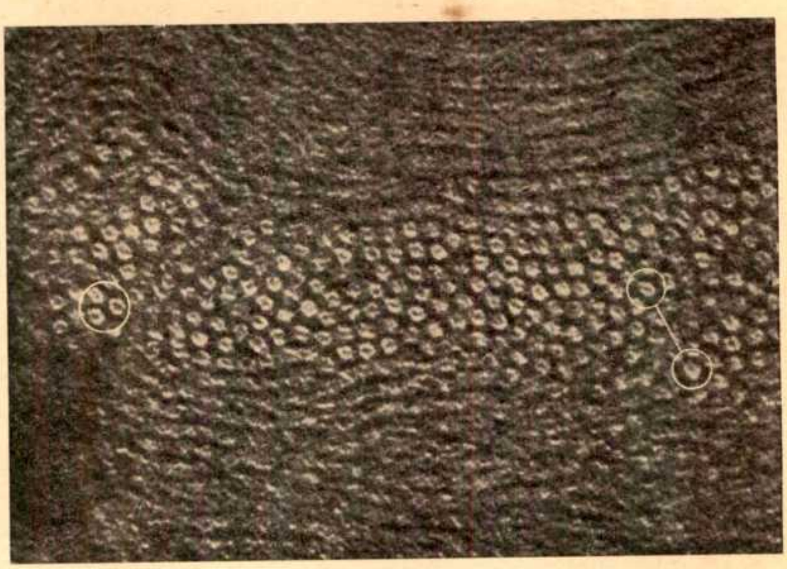

Fig. 1. African porcupine quill-tip. Reduced and treated in osmium tetroxide. Transverse section. (× c. 350,000)

Porcupine quill tips were treated in 0·5 *M* sodium thioglycollate at 35° C. and *p*H 4·6 for 18 hr. and, after washing, in 1 per cent unbuffered aqueous solution of osmium tetroxide for 10 days, a standard procedure was used for embedding[17] (in 'Araldite') and sections were obtained on the Cambridge Huxley-type ultramicrotome with a diamond knife. The sections were examined in a Siemens Elmiskop I electron microscope, using the double condenser, a 50-μ objective aperture, an accelerating potential of 80 kV. and instrumental magnification × 82,500. The astigmatism was corrected and the usual precautions were taken to reduce the effect of contamination. Fig. 1 is a typical electron micrograph considered to be nearest to true focus, in a particular 'through-focus' series, showing in the central portion clearly defined microfibrils the diameter (D) of which (see Fig. 4) and separation (S) were determined from about a hundred measurements, by two observers, as 70 Å. ($\sigma = 5·0$ Å.) and 83 Å. ($\sigma = 7·6$ Å.), respectively. Fig. 1 is a direct print from the original electron micrograph; therefore, the dense areas would be usually considered as corresponding to a metal-containing, thus electron-opaque, matrix[18]. The amount and disposition of the fine detail, now observed in the microfibrils, which are, in any event, clearly resolved only in a relatively small fraction of the total cross-sectional area, varies considerably, as seen from Figs. 2 and 3 which represent, at × 1,650,000, the two encircled areas of Fig. 1. To obtain better contrast, Figs. 2 and 3 were printed from an intermediate plate, consequently the regions containing metal would be usually identified as white areas. The separation (a) of the sub-units, in this case, was estimated to be lower than 20 Å., but it has not been possible to determine the exact number of the sub-units within an individual microfibril or to observe any typical form of their packing in other areas of the transverse section.

However, if a particular arrangement of one type of sub-units could be accepted as possible, it should be compatible with the X-ray diffraction results in both the low- and large-angle regions, and not in the latter only[8]. Indeed, it is not necessary to insist on the presence of a fixed number of aggregates of the α-helices in the microfibrils, as packing would not be very regular in such fibrous tactoids, formed from long molecules of unequal lengths[19]; thus, imperfections of fine detail could be considered as due to some local discontinuity in the sub-units of α-helices, as distinct from an amorphous segment in the microfibril as a whole[20,21]. However, the origin of effects observed in our electron micrographs must rather be sought in the regularity of distribution of heavy elements in the specimen[22]. The consideration of such possibilities directed our attention to the origin of contrast in periodic structures which is known to change in a through-focus series of electron micrographs[23], and it is, perhaps, not surprising that similar effects were observed in the present case of the paracrystalline lattice of keratin.

Figs. 2*b* and 3*b* correspond to a change in focus $\Delta f = 0·1\mu$ (the smallest instrumental step available) from that in Figs. 2*a* and 3*a*, respectively. It can be shown that de-focusing by twice this amount should not affect the resolution of an extended object of about 10 Å. in diameter, but only its contrast[24,25]. The following typical changes are evident, after de-focusing, in the central region (C) of the microfibrils: (1) a small increase in contrast between Figs. 2*a* and 2*b*; (2) the appearance of the fine detail in Fig. 3*b*, which was absent in Fig. 3*a*. In the peripheral regions there is some loss in contrast between the sub-units (P), and this effect can be seen more clearly in the original prints of Figs. 2*a* and 3*a* and Figs. 2*b* and 3*b*, respectively. Both these effects were recorded in numerous microfibrils.

Observations of this kind stress again the necessity for the great care required in the interpretation of electron micrographs. For example, attention has been directed to the fact that observation of a periodic repeat, of dimensions comparable with the resolving power of the electron microscope, cannot be considered as conclusive evidence of a periodic structure

of the identical dimensions in the specimen[26]. To obtain a true record of such a periodic structure it would not be correct to determine the position of true focus using as a criterion Fresnel diffraction along the edges of the specimen, because the phase relationship in the wave-front is modified by a periodic structure of the specimen, so that an appropriate amount of de-focusing is required[27]. It must, of course, be remembered that out-of-focus images of a non-periodic fine detail in the specimen are affected by Fresnel diffraction, which introduces greater contrast[28]. However, it would appear that the changes described by us are, at least in part, due to phase effects enhanced by some regularity in the arrangement of metal in the microfibrils. Indeed, it has been suggested that a row of *n* atoms, parallel to the direction of the electron beam and contained within a cylinder of a diameter smaller than the resolving power of the electron microscope, would produce contrast directly proportional to their number (*n*) (ref. 24).

We are not able to decide at this stage to what extent the variable fine detail in the microfibrils could be due to the structural heterogeneity of keratin or other factors such as orientation of the microfibrils with respect to the direction of the electron beam. Similarly, although we know that the layered structures, originally observed in our early fragmentation experiments, are endowed with strong cross-linkages which had to be broken before the individual microfibrils could be isolated[29], certain features of the images of these regions now revealed in the transverse sections could well be due to other causes[30]. We are, therefore, carrying out a series of experiments which have in the past been applied extensively to solve similar problems in the case of electron microscope images of crystals.

Whatever the outcome of this work, some important conclusions can be drawn from a comparison between electron micrographs of porcupine quill and the para-cortex of Australian merino wool. Though distinct microfibrils appear in greater numbers in the latter, only a relatively small fraction of the total area of the cross-section of porcupine quill shows this type of structure. Since the X-ray diffraction evidence is interpreted to indicate greater regularity of organization in porcupine quill than in merino wools, it could be considered as indirect evidence that the layered regions are endowed with greater regularity than those with arrays of isolated microfibrils.

We have originally suggested[29] that there are three distinct stages in the fragmentation of keratin by the combined chemical and mechanical methods: (1) separation of ribbons or sheets of microfibrils; (2) isolation of microfibrils; (3) breakdown of the latter into 'globular' units. Globular debris observed at the second stage of fragmentation was regarded as originating from the intermicrofibrillar matrix and we tentatively identified it with the fraction rich in sulphur, which can be isolated from keratin following disulphide bond breakdown by oxidation[29]. The evidence presented here and that obtained earlier for wool[4] and feather-keratin (Rogers, G. E., private communication) do not favour a recent suggestion that some feather-like elements could be present around each microfibril of α-keratin[31]. If it were so, changes in contrast in the fine detail should be observed in the matrix, in the out-of-focus position, similarly to those visible in the periodic elements. There is at present no direct conclusive evidence to indicate the type of structure in the matrix. However, we would like to recall that from experiments involving detailed analysis of supercontraction phenomena, we have concluded that the matrix must necessarily possess a certain degree of orientation of its chains to be capable of contraction, in parallel with the microfibrils[32]. Thus, it is not possible to accept conclusions, from the experiments even less direct than the electron microscope evidence, which are considered to imply that microfibrils and matrix possess two distinct structural characteristics and functions[20,21].

It may be of some interest to add that calculations, based on a consideration of the elastic scattering of electrons in extended non-periodic objects containing heavy elements[28,33], have yielded results of the correct order of magnitude for the maximum thickness of the transverse sections of keratin containing osmium[14] and silver[11]. However, some guesswork was unavoidable to allow for absorption by the cuticle cells, membrance complexes, nuclear remnants, etc.

It has been suggested that any attempts to determine the amino-acid composition of various fractionation products of keratin are of little value because of uncertainty as to their histological origin[34]. Yet there is still a tendency to regard 'α'-keratose as derived from the microfibrils and γ-keratose, rich in cysteic acid, from the surrounding matrix. While agreeing that there has been considerable concord between the electron microscope and chemical evidence on this latter point, we would like to direct attention to disconcerting conclusions which emerged from the analysis of data of Corfield *et al.*[35], showing that there is a greater proportion of the bulky amino-acid residues[36] in 'α'-keratose than in γ-keratose; the opposite result to that which would be expected from the general assumption of greater regularity and better packing of the chains inside the microfibrils and in the layered regions.

Finally, we have already stated that it was not possible to determine the exact number of sub-units within a microfibril of porcupine quill. However, even if a 3-strand rope could be identified with the sub-unit, the diameter of our microfibril is too small to accommodate a '9 + 2' system of ropes. Furthermore, other systems of packing of the latter units would result in an inordinately low value of the calculated density. It would appear that the required density could be obtained by accepting the recently suggested packing of the coiled-coils without rope twist[37]; a concept akin to the idea of a discontinuous helix[38].

We thank Prof. J. B. Speakman for his encouragement and continuous interest, Mr. H. J. Woods for numerous discussions, and Mr. M. G. Dobb for his invaluable help in the preparation of specimens. We acknowledge our indebtedness to Dr. G. E. Rogers for allowing us to examine the manuscript of his paper prior to its publication (ref. 4), and the Wool Textile Research Council and the International Wool Secretariat for grants which enabled this work to be carried out.

A SYSTEM FOR CONTINUOUS MEASUREMENT OF RADIOACTIVITY IN FLOWING STREAMS

By E. RAPKIN and J. A. GIBBS

Packard Instrument Co., Inc., La Grange, Illinois

AN apparatus for the determination of β- or α-radioactivity in either circulating liquid or gas streams has been developed. The well-known principles of coincidence type liquid scintillation spectrometry offer an attractive approach to such determination in that backgrounds are generally low and counting efficiencies high. By now the electronics are well established and reliable and are available in many laboratories.

Steinberg[1,2] noted that solid anthracene crystals (blue-violet fluorescence) suspended in aqueous solution containing radioactivity gave relatively high counting efficiencies for carbon-14 and low but usable efficiencies for tritium measurement. He proposed that his method be used whenever it was difficult or inconvenient to solubilize the solution to be counted in one of the more usual liquid scintillation solvents. Afterwards, Karmen and Tritch[3] described a detector filled with silicone-coated anthracene for use in the observation of radioactive components in the effluents from gas chromatography columns. The counting efficiencies obtained for carbon-14 are high and the lower counting efficiencies observed for tritium are attributed to the low tritium β energies and absorption of tritium β's by the silicone coating.

Rapkin and Packard[4] confirmed Steinberg's original report and offered some preliminary results on determination of both carbon-14 and tritium activity in flowing streams wherein these streams were passed over anthracene crystals placed between two photomultipliers and observed in the fashion which is by now well known. Recently, in independent investigations, Scram and Lombaert[5-7] have likewise examined the continuous measurement of β-activity using microcrystalline anthracene as the scintillator. We would like to extend the earlier observations of Rapkin and Packard and to report not only on the use of solid anthracene crystals for the measurement

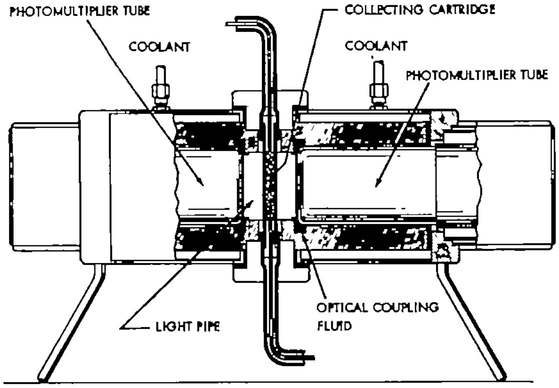

Fig 1. The continuous flow detector a simplified drawing

of activity in flowing liquid streams, but also the measurement of activity in gas streams.

A detector was constructed which is shown in simplified form in Fig. 1. A 'Lucite' light pipe coated the titanium dioxide, which was made according to the suggestions of Horrocks and Studier[6], was coupled to two photomultipliers which were in turn fed to appropriate coincidence type circuitry. The detection cell, consisting of a glass tube 9 mm. outer diameter with appropriate fittings on either end, was packed with anthracene crystals. A glass frit, or glass wool, was incorporated in the cell on the downstream side to contain the anthracene and a pledget of glass wool was placed above the anthracene on the upstream side.

The electronics took one of two forms. Initially, a Tri-Carb spectrometer was used and was operated on a pre-set time basis automatically recording counts which were accumulated during the counting period. For graphical presentation a special rate-meter was constructed. It is essentially identical to the circuitry of the Tri-Carb spectrometer except that the scalers and timers have been removed and replaced by two rate-meters. Two channels of analysis are possible. They may both be observing identical portions of the energy spectrum, or widely differing parts may be monitored by each. Separate amplifiers are used on each channel with continuous gain controls, so that for dual-label experimentation one channel may be operated at maximum gain to observe the less energetic isotope, while the second channel is operated at reduced gain to observe the more energetic.

In order to determine counting efficiency, it is always necessary to know the amount of material being measured. In a device such as that which we described, the determination *in situ* of the volume of voids in the sensitive zone necessitates indirect measurement such as that advocated by Schram and Lombaert[7]. To circumvent indirect measurements and to afford standardization of technique, our preliminary studies were made using sealed tubes approximating the size of the detection cell which were filled with anthracene crystals and a radioactive chemical containing a known number of disintegrations per minute (d.p.m.). Fig. 2 shows the excellent straight-line relationship which was observed between total activity and counts observed with varying amounts of both $^{14}CO_2$ and tritiated methane. Carbon-14 counting efficiency was of the order of 50 per cent with a coincident background from 100 divisions to infinity of less than 40 c.p.m. at 900 V. Tritium counting efficiency was in the range of 7 per cent and the integral background from 100 divisions to infinity was about 90 c.p.m. at 1,130 V. Using a plastic scintillator, Boyce *et al.*[9] report a counting efficiency of tritium gas of 2·2 per cent with a coincident background of 300 c.p.m.

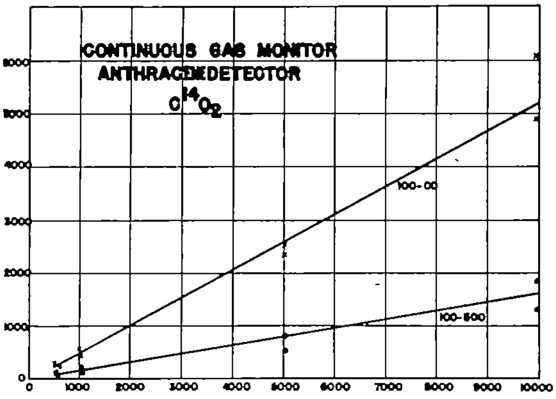

Fig. 2. A linear plot illustrating the continuous measurement of radioactive carbon dioxide using crystalline anthracene as the scintillator

The approach used to test the system for application to liquids was the same as that used with bases. For aqueous solutions of carbon-14 benzoic acid integral counting efficiencies in excess of 50 per cent were observed; but it was necessary to operate at higher voltages and with somewhat higher backgrounds. For tritium measurement, using tritiated water as a reference material, performance was somewhat erratic and under the best conditions efficiencies were between 1 and 3 per cent over a wide range of activity.

The detector described here has now been further tested in closed flowing systems. For liquid-flow determinations when used in conjunction with commercial amino-acid analysers of the Spackman[10] or Piez[11] design, carbon-14 differential counting efficiencies of 20–30 per cent have been experienced with a background of about 20 c.p.m. With discriminator settings of 100–500 divisions, peaks containing as little as 300 c.p.m. (less than $1\cdot5 \times 10^{-4}$ μc.) are readily observed and once the peak has passed through the detector, absolutely no activity remains in the detection zone. Even with sharp peaks containing as much as 20,000 d.p.m. there was no residual activity evident and background immediately returned to base-line. Resolution of the

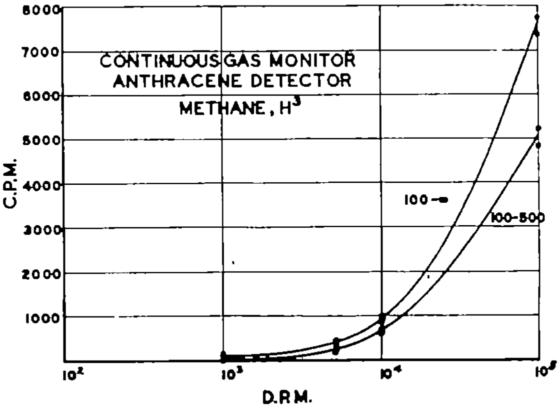

Fig. 3. A semi-log plot illustrating the continuous measurement of tritiated methane using crystalline anthracene as the scintillator

amino-acid analyser was unimpaired by insertion into the system of the small volume detector described. The optimal volume which we have determined for the detection zone when the detector is operated in conjunction with an amino-acid analyser is approximately 1 ml. This observation is in agreement with the results of Schram and Lombaert[7].

For gas analysis we have used the 1-ml. cell, and for breath analysis we have also constructed a cell with a free space after packing of about 10 ml. We have begun some preliminary work in which the atmosphere about a fermentation broth is continuously circulated through the detector and back into the fermenter. A record of evolved activity is obtained.

SCATTERING OF UNDERWATER SOUND IN SAANICH INLET, BRITISH COLUMBIA

By B. M. BARY

Institute of Oceanography, University of British Columbia, Vancouver

W. E. BARRACLOUGH

Pacific Biological Station, Nanaimo

AND

R. HERLINVEAUX

Pacific Oceanographic Group, Nanaimo, British Columbia

BACK-SCATTERING of the ultrasonic pulses of echo-sounders is usually attributed to reflexion of sound-waves from planktonic or nektonic organisms[1,2]. It is recorded as 'blips' on the echogram, and is a common phenomenon in the sea. Single animals, such as fish, or a small group of organisms produce few blips, so that a compact, well-defined trace may result. Or, blips may be numerous and continuing when a more-or-less diffuse, layer-like record is obtained. The nature of this record seems to depend on several factors such as the numbers of the organism present[3] and the relation between the sonic frequency (length of the wave) and the cross-sectional area and acoustic properties of the organisms[4]. The latter factors in turn are related to the structure and composition of the exoskeleton and body, and particularly to the inclusion of gas bubbles or other compressible, highly reflective substances[5]. A wide range of organisms has been inferred as causes of scattering; but only a few direct observations have been made, using underwater cameras or television[6].

The problem of relating cause and effect appears to be due to difficulties encountered when working in the open sea. A layer may occur only spasmodically or may not be available readily to the observers, so that a continuing examination is not possible. Sampling presents numerous problems, not the least of which is knowing whether the organisms collected were the effective scatterers on a particular occasion[7,8]. Furthermore, the relationship between pelagic organisms and their environment is a dynamic one which can lead to short- and long-term fluctuations in the species composition of the layer and in its structure, depth of location or expanse[8].

These and related problems could well be examined more effectively in a scattering layer in which comparatively few species are effective scatterers and the species composition is not subject to excessive change. Additional advantages would accrue if the areas concerned were accessible, the layer a permanent feature, and the oceanographic conditions reasonably stable. Accumulating evidence has suggested that such conditions apply in Saanich Inlet, Vancouver Island, British Columbia. Accordingly, an investigation of the scattering layer there has been undertaken.

Saanich Inlet is a fjord, approximately 24 km. long and from 0·5 km. wide in the upper to 6 or 7 km. wide in the lower reaches; the mouth is about 3 km. wide. A sill across the mouth is about 75 m. deep; inside the sill and extending along the length of the inlet for 16 km. are depths near, or in excess of, 200 m.

Two years of observations of temperature, salinity and oxygen[9] indicate that exchange of water between the inlet and outside (Georgia Strait) is slow; periodic flushing of deeper waters has not been observed. Hydrographic conditions therefore appear to be relatively simple. However, an unusual feature (in British Columbian inlets) is the presence of water deficient in oxygen, typical values being 0·1–0·2 ml./l. The deficiency becomes apparent at depths between 80 and 100 m. and extends to the bottom[9]. This condition may be contributed to by substantial quantities of organic material, mostly crustacean exoskeletons, which are found below the scattering layer and are apparently settling on to the bottom. This material is probably in continuous supply and it may well be in excess of the oxygen available for its aerobic decomposition in a water body in which renewal is slow.

Preliminary investigations have included surveys of the scattering layer throughout the inlet. An *EDO* sounder (12 kc./s.), associated with a precision depth recorder, was used for elucidating changes in the density of the scattering and the distribution of the layer in time and place. Sampling of the planktonic organisms was carried out below, in and above the layer, using the 'Catcher', a high-speed closing sampler[10], towed horizontally at speeds between 4 and 8 knots. As well, Clarke–Bumpus samplers, a 1-metre ring net, the Currie–Foxton vertical closing net[11] and a 3-ft. Isaacs–Kidd midwater trawl were used on one or more occasions. A large mid-water trawl with a mouth-opening 11 m. wide was hauled for fish. An echo-sounder transducer was attached to the head rope of the trawl so that it could be fished at any desired depth. It was hauled, usually for 1 hr., at about 2 knots, in conjunction with the plankton tows, but from another vessel.

The presence of a scattering layer in Saanich Inlet has been known for the past two years. It has been investigated briefly on numerous occasions over the past 12 months. The layer is now believed to be a consistent feature of the inlet within which it is confined and over the whole of which it appears to extend. However, the density of the scattering varies from place to place and apparently may do so from day to day at selected positions. The layer lies above the oxygen-deficient water; during daylight it is well defined and about 38 m. deep with its upper surface at about 72 m. After sunset (as detected by a 30-kc./s. Kelvin–Hughes, model 29 *F*, sounder) it has been shown to rise to the surface as a layer at a rate of about 2 m./min. With the 12-kc. *EDO* sounder, on an occasion several weeks later, the scattering appeared to diffuse upwards until its density was more or less uniform between the day-level of the layer and the surface. These differences may be due to changes in the behaviour of the organisms in the layer with time or they may be more apparent than real and result from the use of frequencies of 30 and 12 kc./s. Clearly, problems are posed concerning the biology of the organisms causing the scattering and the nature of the scattering and its relationship to the frequency of the pulse.

Results from the plankton hauls with the catcher (when a net of 10 meshes/in. was used) indicate that euphausiids and amphipods are the predominant 'large' organisms' of the layer along with rare occurrences of shrimp, medusæ, ctenophores and small squid. Of these, one species of euphausiid (*Euphausia pacifica* Hansen, 1·5–2·5 cm. long) and one species of gammarid amphipod (*Orchomenella* sp., 1·5–2 cm. long) far outnumbered any others collected. *Euphausia pacifica* occurred in numbers up to 175/m.^{3} of water filtered, and the gammarid up to 27/m.^{3}. These two species constituted as much as 95 per cent of the total organisms of samples from within the layer (excluding Copepoda, which were not collected in representative numbers by the net of 10 meshes/in.). Biomass was determined on the basis of the wet-weight (filtered and drained) of the total fauna collected with the net of 10 meshes/in. The biomass was nil in oxygen-deficient water; 0·03 gm./m.^{3} just below the layer, 0·01 gm./m.^{3} above and clear of the layer, and 5·2 gm./m.^{3} within the layer. The latter value is very high when compared with 0·1–0·15 gm./m.^{3} in the Black Sea[12]. Copepods, in samples collected with a net of 40 meshes/in. in the catcher, ranged from the larger *Calanus* spp., and *Euchaeta japonica* Marukawa, down to small species such as *Oithona* spp., and *Microsetella* spp. They occurred in high numbers in the layer, but were almost absent below, and sparse above it. The biomass of the copepods has not been determined; but it is less than that of the euphausiid and amphipod. The other sampling gear collected much the same range of organisms as the catcher, but the samples have not been enumerated in detail.

Stratification of the common species of euphausiid and ampliphod is indicated from hauls made at different depths in the layer; the amphipod appears to have predominated at the lower and the euphausiid at the higher levels. In two night hauls near the surface, only *Euphausia pacifica* was captured.

Three myctophid fish (*Lampanyctus leucopsarus* (Eigenmann and Eigenmann)), up to 6 cm. long, as well as two young hake (*Merluccius productus*), of about 13 cm. length, were captured by the catcher. These two species of fish and others were collected by the large trawl as well.

The 11-m. trawl was fished with the mouth opening either in, or encompassing the lower edge of, the layer. For most of these hauls, the 30-kc./s. sounder had shown few or no traces of fish in association with the layer and totals of only 20–40 fish were collected. These consisted of herring (*Clupea pallasii*), young hake (*Merluccius productus*) about 15 cm. long, whiting (*Theragra chalcogramma*) up to 30 cm., a few dog-fish up to 75 cm., *Sebastodes flavidus* and *S. diploproa* 35–40 cm. long, and a few myctophids. On one occasion, scattering attributed to fish was detected immediately below the layer. In a haul of 10 min. through this the catch was in the vicinity of 1,000 lb., consisting of hake, dogfish and a few rockfish (*Sebastodes*). It would seem from these results that fish were not the main cause of the scattering during the period these collections were made. Equally, they contributed to it at times and must be considered as potential scatterers in the layer.

The guts of a number of the fish were examined. A few were empty and the fish may have disgorged, or had not been feeding recently; most contained either the common amphipod or euphausiid or both. The same applied to the stomach contents of a 1·5-kgm. salmon (*Oncorrhynchus kisutch* (Walbaum)) and 0·8-kgm. smelt ((*Hypomesus pretiosus* (Girard)) caught in daylight on a rod and line.

Because the scattering layer in Saanich Inlet is accessible continuously, several features may be investigated. The ecology and biology of the plankton and the fish can be studied to establish relationships between species throughout the year and their distribution in relation to the layer, as well as their distribution horizontally and vertically within the inlet. Relationships of the organisms in the layer to hydrographic conditions must be established, especially to the oxygen-deficient water; it may be possible to demonstrate as well, from field observations, the tolerances of species to low oxygen content.

The determination of the manner whereby scattering is effected can be attempted, and an investigation made of the effects obtained when using a range of frequencies in conditions which are known.

A SIMPLE SURFACE POTENTIAL METHOD FOR THE DETERMINATION OF SMALL METAL FILM AREAS

By DR. J. PRITCHARD

Department of Chemistry, Queen Mary College, London, E.1

EVAPORATED metal films deposited at low temperatures and partially stabilized by gentle annealing have been widely used to investigate chemisorption. A typical film may weigh 5–10 mgm. with a geometric area of 50–100 cm.^{2} and a true area of the order of 10^3 cm.^{2}, determined by the Brunauer–Emmett–Teller (B.E.T.) method with krypton Improved stability and uniformity of the surface may be obtained by further sintering or by deposition at higher substrate temperatures. The true area may then be only twice the geometric area and the B.E.T. krypton method will be inaccurate unless the volume of the system is very small. This limitation is inconvenient, preventing, for example, the use of an ionization gauge. An alternative is to use another adsorbate with a lower vapour pressure. Thus, ethane[1] has been used at −183° C. on copper films. The method is limited to those cases where the chosen gas does not react chemically with the films. Only an inert gas could have general applicability. Xenon has a low enough vapour pressure at either −196° C. or −183° C., but is difficult to obtain without krypton as an impurity. Preliminary experiments with xenon at −183° C. on a nickel film with an area of about 10^3 cm.^{2} showed that the krypton impurity accumulated in the gas phase. This complication and the need for precise temperature and pressure measurement are avoided by the following method.

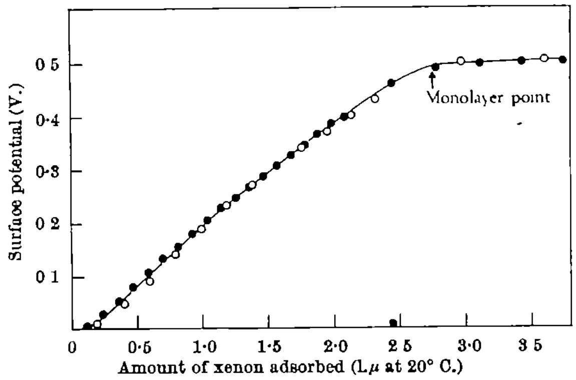

Fig. 1. Adsorption of xenon at −183° C. (full circles) and −196° C. (open circles) on a gold film deposited at −183° C. and sintered at 60° C.

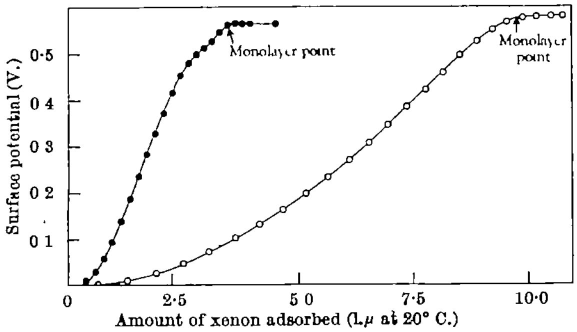

Fig. 2. Adsorption of xenon at −183° C. on a copper film deposited at −183° C. after sintering at −78° C. (open circles) and 60° C. (full circles)

The surface potential of adsorbed xenon[2] may be measured very simply by the diode method, the only necessary addition to the film vessel being a small tungsten cathode at the bulb centre. For metals such as copper and gold the cathode may even serve as the evaporation source. The method of measurement has been described in detail elsewhere[3,4]. Initial experiments with gold films showed a nearly linear dependence of the surface potential on coverage up to a point beyond which the surface potential changed very little and simultaneously a small, but growing, pressure was detectable with a Pirani gauge. It seems reasonable to associate this point with completion of the monolayer, and the succeeding nearly non-polar adsorption with second layer formation.

Early data of Mignolet[5] indicated that pre-sorbed gases reduce the xenon surface potential. Ehrlich and Hudda[6] conclude from field emission studies that the binding energy of an inert gas atom depends critically on how closely it may approach the metal atom array. Because of the relatively large size of the xenon atoms in the first layer it is probable that second-layer atoms are much less polarized and less strongly bound than the first-layer atoms, the strong polarization on clean surfaces of which is indicated by the surface potential. Thus we might expect the monolayer to be practically complete before second layer adsorption starts. This condition is required by both the B.E.T. and the present method if reliable monolayer volumes are to be obtained. In agreement with the ideas of Ehrlich and Hudda it is found that the maximum xenon potential is considerably reduced after sintering.

For the clean surfaces so far examined (copper, gold, nickel, platinum ?) the monolayer point at −183° C. has been reached before a significant pressure (~ 3×10^{-5} mm. mercury) developed. At this pressure the amount of xenon in the gas phase is about 10^{-3} l.μ compared with an adsorbed quantity of one l.μ or more. Neither volume calibration nor accurate pressure measurement is required. A further useful feature of the method is that the result is independent of temperature between −196° C. and −183° C., as shown for a gold film in Fig. 1. Liquid air of any composition may therefore be used. The monolayer point is not always as obvious as in the case of gold or copper (Fig. 2); but in practice the point at which doses of xenon fail to affect the surface potential is quite clear in such cases as nickel (Fig. 3).

The result for platinum (Fig. 3) is probably unreliable. The film was extremely thin and gave only a small positive surface potential with hydrogen instead of the negative effect observed by Mignolet[7] for clean platinum films. Thus the small positive gradient following the monolayer point may be due to second layer xenon adsorption or to xenon adsorbed

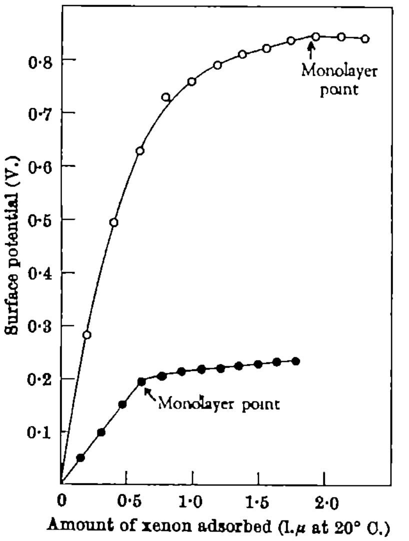

Fig. 3. Adsorption of xenon at −183° C. on a nickel film (open circles) and a platinum film (full circles)

above impurities, the 'monolayer' then being xenon adsorbed between impurity atoms. The very small apparent monolayer volume is noteworthy. In general it is found that pre-sorbed gases markedly affect the apparent monolayer volume and the maximum xenon surface potential. The effect appears to be one of exclusion and gives useful information on the arrangement of adsorbed molecules on the surface. When xenon is totally excluded from direct contact with the metal, for example, in the case of copper saturated with carbon monoxide, it is impossible to determine a monolayer volume as adsorption occurs only at higher pressures and with scarcely any surface potential. Pre-sorbed hydrogen does not appear to affect the xenon monolayer volume.

Having obtained a xenon monolayer volume, a value must be assumed for the effective area of a xenon atom in order to obtain a surface area. A comparison of the lattice constants of crystalline krypton and xenon suggests a ratio of 1 : 1·22. A variety of values has been used for the effective area of a krypton atom. A value of 19–20 Å.[2] appears to be widely accepted. On this basis the area of a xenon atom may be taken as 24 Å.[2]. To check this point a copper film of about 10 mgm. weight was deposited at −196° C. and stabilized by keeping at −78° C. for a day. The film area was then determined by the B.E.T. method with krypton at −196° C., and by the xenon method at −183° C., the respective monolayer volumes being 26·5 l.μ and 21·3 l.μ respectively. These values are consistent with the value 24 Å.[2] for the area of the xenon atom. The absorbed volumes are quoted in units of litre-micron (l.μ) at 20° C. Each unit is thus equivalent to an area of 79 cm.[2].

I thank Mr. W. A. Crossland for assistance with the comparison of the krypton and xenon areas.

VARIATIONS OF SCALE HEIGHT IN THE UPPER ATMOSPHERE

By D. G. KING-HELE

Royal Aircraft Establishment, Farnborough

THE 'density scale height' H in the upper atmosphere is a measure of the rate at which air density ρ varies with height y, being given by $H = -\rho/(d\rho/dy)$. The value of H, which is important because (together with the molecular weight of the air) it determines the air temperature, is not yet well established at heights above 200 km. The most popular method for evaluating H is from the slope $d\rho/dy$ of the curve of air density (or electron density) versus height; but measurements of this slope are inevitably somewhat inaccurate, because of the errors in ρ.

There are two other viable methods for finding H: (1) from the decrease in the perigee distance r_p of an artificial satellite; (2) from the decrease in the orbital period T of a satellite in a small-eccentricity orbit. Both methods are potentially accurate, since the decreases in r_p and T are directly proportional to H—the decrease in r_p, for example, being given to a first approximation by[1]:

$$r_{p0} - r_p \simeq \tfrac{1}{2}H\ln\frac{e_0}{e}$$

for eccentricities e between 0·02 and 0·2, where suffix 0 denotes initial values. Previous attempts to use these methods[1–3] were not entirely successful, partly because of poor data and partly because the theory needed further refinement. Recently the methods have been further developed[4], taking into account the effects of: (1) the third, fourth, fifth and seventh harmonics in the Earth's gravitational potential; (2) atmospheric oblateness[5]; (3) lunisolar perturbations; (4) the variation of H with height. The methods were then applied to all suitable satellites for which adequate orbital information was available, and the 44 values of H obtained, corrected to 'average day/night' conditions, are shown in Fig. 1. Most of these values are independent of each other, in the sense that they stem from independent values of r_p and T. The points in Fig. 1 fall into a consistent pattern when grouped according to year, as shown by the encircling broken lines, and indicate that the value of H (at a given height) decreased considerably as solar activity declined between 1958 and 1961.

In Fig. 2 curves drawn through the three groups of points in Fig. 1 are shown (unbroken lines), together with selected values from other sources. The 1958 unbroken curve refers to early 1958, since all the relevant points in Fig. 1 are for dates between January and May; similarly, the relevant 1959 points

Table 1. SCALE HEIGHT h AND TEMPERATURE τ, FROM THE VALUES OF H IN FIG. 2

Year	Early 1958			Early 1959			1960–61			Error per cent
Height (km.)	200	250	300	250	350	450	270	350	450	(*S.D.*)
h km.	51	61	66	50	61	64	45	58	57	5–10
M (ref. 7)	27	26	24	26	22	19	25	22	19	10 ?
τ °K.	1,530	1,720	1,680	1,400	1,400	1,230	1,220	1,230	1,090	10–15 ?

are for January–June; and the 1960–61 points cover dates between June 1960 and August 1961. It is estimated that the unbroken curves represent H with errors (*S.D.*) of 5–10 per cent.

Of the other curves in Fig. 2, the broken line shows the values of H in the COSPAR International Reference Atmosphere[7], which refer to 1959 and agree quite well with the early-1959 unbroken curve, though of opposite curvature. The values for late 1960 from ref. 8 (line of short dashes) also agree to within 7 km. with the 1960–61 unbroken line, though obtained by a completely different method. It was noticed[9] in 1959, and has since been confirmed by various authors[8,10–12], that the variation of H with height exhibited a pronounced minimum at some height between 200 and 300 km., as is apparent from the values from refs. 8 and 10 plotted in Fig. 2. The new results for 1959–61 are consistent with these previous findings, since they indicate low values of H (about 35 km.) at heights near 250 km., so that some pause in the increase of H with height is needed for a satisfactory link-up with the values shown at heights below 170 km., which are generally assumed[12] to be little affected by solar activity.

Fig. 2 also shows that, although H continues to increase with height up to 450 km., the rate of increase is much slower above 350 km. This tendency is also evident in refs. 6 and 8, though most other authors (for example, refs. 7, 12–15) have obtained or assumed near-linear increases of H with height in this height-band.

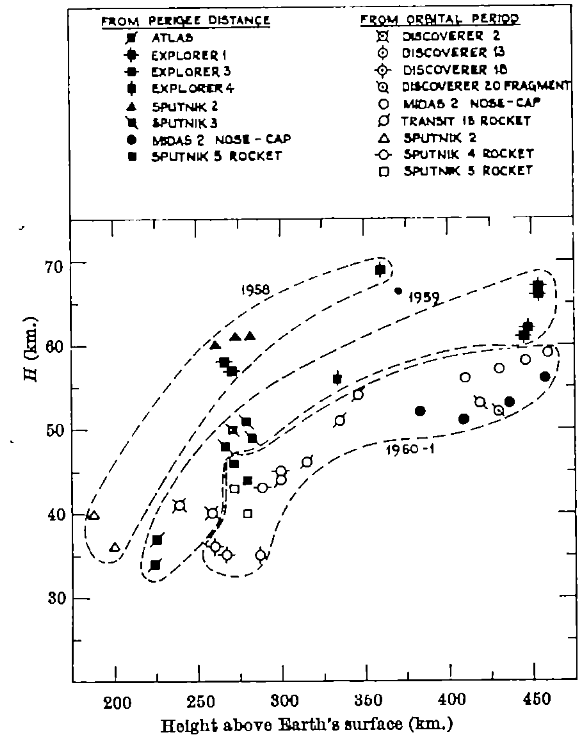

Fig. 1. Values of density scale height H obtained from the changes in perigee distance and orbital period of various satellites

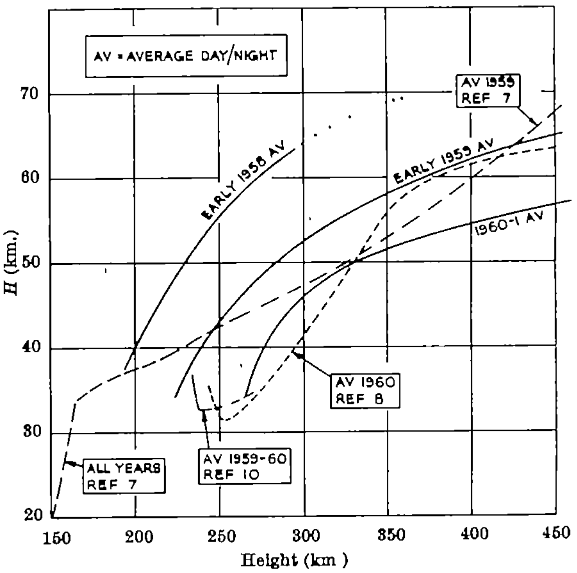

Fig 2. Values of H obtained from Fig. 1 (unbroken lines) compared with selected values from other sources

The scale height h of the upper atmosphere, as usually defined, differs slightly from H, being given by $h = -p/(\mathrm{d}p/\mathrm{d}y)$, where p is the air pressure. From the equation[16] between h and H, it is possible to derive values of h from the curves of H in Fig. 2. If the mean molecular weight M of the air is also known, the air temperature τ can be found. The currently accepted values of M may, however, be in error by perhaps 10 per cent (*S.D.*). Table 1 lists values of h, and also values of τ obtained on taking M from ref. 7.

Thus, between early 1958 and 1960–61, the average day/night temperature at heights of 250–400 km. appears to have decreased by about 500° K. The temperatures obtained here show a maximum at a height between 250 and 300 km., that is, near the maximum of the F_2 layer of the ionosphere; but this is probably not significant, in view of the possible errors.

A full account of this work[4] will be published elsewhere. The results could be greatly improved, both in scope and in accuracy, if more accurate orbits were available for short-lifetime satellites.

LETTERS TO THE EDITOR

ASTROPHYSICS

Terrestrial Accretion from the Solar Wind

A SERIES of communications has appeared in *Nature* under the above title. We would like to discuss in particular those by de Turville[1,2], who has proposed that the oceans have resulted from the accretion of solar protons, and that by Frith[2], who summarized recent data on stratospheric water-vapour content and showed that this substantiated the hypothesis of de Turville. We will discuss three main points and cite several others, the combination of which seems to indicate that no more than a minor fraction of the water present in the world's oceans has resulted from the accretion of protons from the solar wind. Our main points are these: (1) The solar wind has been measured, and the flux is a factor 10 lower than that used by de Turville in his first communication, and a factor 100 lower than the value used in his second communication. (2) de Turville fails to consider the possibility of escape of hydrogen from the exosphere, which, even if his other assumptions were correct, means that his accretion value is only an upper limit. (3) The observed increase in the water-vapour mixing ratio in the stratosphere cited by Frith does not necessarily mean that the water is of extra-terrestrial origin. There is evidence of large-scale vertical exchange processes in the polar winter stratosphere which can transport the moisture aloft.

The flux of positive particles outside the Earth's magnetic field has been measured by American and Russian space probes. The most extensive Russian data were taken by *Lunik II*. This work was reported by Gringauz *et al.*[3], who quote positive particle fluxes of about 2×10^8 cm.$^{-2}$ sec.$^{-1}$. The American measurements were recorded by *Explorer X*, and were recently reported by Bridge *et al.*[4]. They gave fluxes which varied between 5×10^6 and 10^9 cm.$^{-2}$ sec.$^{-1}$, with an average value of about 4×10^8 cm.$^{-2}$ sec.$^{-1}$. The flux $(n_1 v_1)$ assumed by de Turville in his first communication[1] was $5{\cdot}05 \times 10^9$ cm.$^{-2}$ sec.$^{-1}$ and the value used in the second communication[2] was $4{\cdot}75 \times 10^{10}$ cm.$^{-2}$ sec.$^{-1}$. His values are thus respectively one and two orders of magnitude too large, and the Earth could only accumulate the mass of the oceans during geological time by capturing all protons out to 30 Earth radii, or if fluxes of about 10^{12} cm.$^{-2}$ sec.$^{-1}$ are present in cosmic-ray events associated with solar flares. The latter seems unreasonable in the light of Van Allen's[5] measurements of high-energy ($E > 30$ MeV.) particle fluxes of 2×10^4 cm.$^{-2}$ sec.$^{-1}$ during the strong November 12, 1960, events. Furthermore, as Harrison[2] has pointed out, most authorities expect that the Earth's magnetic field will exert a shielding effect, rather than tend to capture solar particles.

The rate of escape of hydrogen from the Earth's atmosphere is very difficult to calculate, as this rate is dependent on two factors which can only be estimated. These are the concentration of hydrogen and the temperature at the base of the exosphere. However, it is known that both helium-3 and helium-4 do escape. The production-rate of these gases can be estimated within certain limits and they, together with the known concentrations, give atmospheric residence times of the order of 10^7 years[6]. Residence times of this magnitude imply that the atmospheric concentrations represent a steady state determined by escape and production. Thus it is certain that a fraction of hydrogen present in the high atmosphere will be lost, whether it comes from dissociation of water or from the solar wind.

The rate of escape of hydrogen at the base of the exosphere must be balanced by the sum of the hydrogen flux from lower layers, where an equilibrium with oxygen and water is present, and the accretion from the solar wind. Depending on the conditions the hydrogen flux from the lower layers can be positive or negative, but at present we are not even able to attempt to estimate the sign of this flux. Certainly, any amount of hydrogen which could be established as being captured by the Earth (and its magnetic field) can only be an upper limit of the actual amount accreted.

Frith[2] cited data which indicate an increase of the water-vapour mixing ratio in the stratosphere above 15–20 km. in low and middle latitudes and newer data[7] tend to confirm this. However, the data available at present do not necessarily show that this water-vapour in the mesosphere is of extraterrestrial origin. The data of water-vapour mixing ratio do not cover the polar regions, and there is increasing evidence that large-scale vertical mixing processes do occur in the polar winter stratosphere which could provide for the required upward transport of terrestrial water-vapour.

Large-scale vertical motions in the polar stratosphere are indicated by the spring rise of ozone and the explosive warmings in late winter. Recent results of the rhodium-102 high-altitude tracer experiment[8] show that, during winter, air from about 60 km. moves down to the lower stratosphere, resulting in an exchange rate of 0·05–0·2 year^{-1}. These downward movements must be counter-balanced by corresponding upward movements, which most likely occur also over the winter pole and which can carry water-vapour from the tropopause to the mesosphere. Average stratospheric temperatures over the winter pole are such that mixing ratios of about 0·03 gm./kgm. air can penetrate to higher layers and this is about the mixing ratio found in 25–30 km. by various methods. If this is the source of stratospheric water-vapour one would not expect the mixing ratio to exceed 0·1 gm./kgm. air, which means that it must remain fairly constant at altitudes above 30 km.

It is interesting nevertheless to assume that the dry layer present at 15–20 km. extends over the entirety of the globe, and to see how much water would have accumulated on the Earth during geological time. We shall assume a constant mixing ratio above 30 km. in the range between 0·03 and 0·1 gm./kgm. air, an exchange-rate above 30 km. between 0·05 and 0·2 year^{-1} (the same limits found by Kalkstein[8] for the atmosphere above 60 km.), and that the age of the Earth is between $3{\cdot}3 \times 10^9$ and $4{\cdot}7 \times 10^9$ years. We thus obtain a lower limit of 23 per cent and an upper limit of 400 per cent of the mass of Earth's oceans accreted throughout geological time, in confirmation of Frith's results. In the light of our previous discussion of measured solar-proton fluxes, expected shielding due to the Earth's magnetic field, escape of hydrogen from the exosphere, and mixing processes which occur in the winter polar stratosphere, it appears that the coincidence of the integrated influx with the mass of the oceans is entirely fortuitous. However, the importance which is attached to an extra-terrestrial origin for even part of the stratospheric water-vapour means that detailed high-altitude water-vapour measurements, especially in the polar stratosphere, could be of great scientific value.

Finally, one should mention that the oceans account for only 0·025 per cent of the mass of the Earth. Urey[9] indicated that an even greater amount of water was probably held in hydrated silicates in the material which formed the primitive Earth. There is geochemical evidence that the Precambrian atmosphere had much less oxygen than is present on the Earth to-day[10]. It seems more likely that the present oxidized character of the atmosphere has resulted from the dissociation of water and subsequent escape of hydrogen, rather than the ultra-violet dissociation of rocks proposed by de Turville[1]. During the early phases of the Earth's evolution, at which time the speed of rotation was faster and free oxygen in low abundance, the former process probably proceeded quite rapidly.

This work was supported in part by U.S. Atomic Energy Commission contract *AT* (49–7)–1431.

•

THE new observations reported by Gringauz and Bridge appear to confirm each other and, if they are correct, the resulting hydrogen accretion-rate will certainly be too small to account for the bulk of terrestrial hydrogen. Moreover, it is now certain that terrestrial deuterium is definitely not due to a slow accretion of solar deuterium. The previously proposed rate of deuterium production at the solar surface (3·3 × 10^{11} atoms cm.$^{-2}$ sec.$^{-1}$) through neutron capture by hydrogen would imply a flux of 2·2-MeV. gamma radiation of 3·5 × 10^{6} photons cm.$^{-2}$ sec.$^{-1}$ at the orbit of the Earth, whereas Northrop and Hostetler[1] have set an upper limit of only 0·5 photon cm.$^{-2}$ sec.$^{-1}$ for this flux. It seems inescapable that terrestrial deuterium was produced *in situ* by neutron irradiation of terrestrial hydrogen at an early stage in the evolution of the solar system, as proposed by Fowler *et al.*[2]. In view of these considerations, and the difficulties raised by oxygen supplies, the suggestion I made earlier concerning the origin of the oceans has lost all plausibility and I wish to withdraw it.

GEOPHYSICS

Orbital Acceleration of Satellites during Geomagnetic Disturbance

JOULE heating of the upper atmosphere can explain the fluctuations of orbital acceleration of artificial Earth satellites with geomagnetic disturbance[1,2].

Consider a model thermosphere in which the height (z) rate of change of scale height, H ($= kT/mg$), is constant, that is, $\mathrm{d}H/\mathrm{d}z = \beta =$ constant ($k =$ Boltzmann's constant, $T =$ temperature, $m =$ molecular weight of gas, $g =$ acceleration due to gravity). Then[3]:

$$p/p_0 = (H/H_0)^{-1/\beta} \qquad (1)$$

where p, p_0 are the pressures at height z and at a base level z_0. Assuming $m =$ constant, it follows that:

$$n = n_0(T/T_0)^{-(1+\beta)/\beta}.(g/g_0)^{1/\beta} \qquad (2)$$

A crude match of the model to the actual thermosphere is suggested by taking $\beta \approx 0 \cdot 6$ (corresponding to $\frac{\mathrm{d}T}{\mathrm{d}z} \approx 10°$ K. per km. or a downward flux of about 1 erg cm.$^{-2}$ sec.$^{-1}$). Neglecting the factor $(g/g_0)^{0 \cdot 6}$ over the height-range of present interest (150–650 km.) we have:

$$n \approx n_0(T_0/T)^{\gamma} \qquad (3)$$

where $\gamma \approx 2 \cdot 7$. This shows the sensitivity of thermospheric densities to density and temperature at the base-level.

At high magnetic latitudes joule heating peaks at an altitude of about 150 km.[4,5] and falls off with a scale length of about 25–50 km. above and below this height. Those electric currents flowing in the ionosphere to cause geomagnetic variations (*Sq*) and disturbance (*Ds* and *Dst*) (see following communication) modulate the density and temperature at this height and hence at all heights in the thermosphere.

The rate of heating, $Q(Sq)$, attributable to *Sq* is about 10^{-8} erg cm.$^{-3}$ sec.$^{-1}$. Elsewhere[6] I have shown that such a Q value can modulate the temperature at 150 km. height (0 level) by tens of degrees K., say 50° K. for sake of calculation. Such a change of T_0 will not greatly affect β when $T_0 \approx 500°$ K. originally. There will be a 10 per cent increase in n_0 due to change of scale height at 0 level. It can be seen from equation (3) that the percentage change in n will increase with height until it is about 30 per cent at 650 km. The rate of heating $Q(Ds)$ in low latitudes appears on the average to be about equal to $Q(Sq)$ (see following communication). Thus the average fluctuations of density attributable to joule heating of the ionosphere can amount to about 20 per cent at 150 km. to 60 per cent at 650 km. This compares favourably with variations actually observed[2], namely, ± 20 per cent at 250 km. and ± 50 per cent at 650 km.

At times of severe magnetic disturbance, conditions common to the auroral zones spread to lower latitudes. At these times Q can rise to order 10^{-6} erg cm.^{3} sec.$^{-1}$

Supplement to NATURE

No. 4823 APRIL 7, 1962 Vol. 194

BEYOND THE 'TWO CULTURES'

Towards a Third Culture

By Charles Davy. Pp. 178. (London: Faber and Faber, Ltd., 1961.) 18*s*. net.

THE conception of two cultures, the humanist and the scientific, has given rise to animated discussion, to which Mr. Davy's book is a welcome contribution because it attempts a constructive understanding of the situation. Two important ideas form the core of his thesis—that of the evolution of consciousness and that of the possible development of a "third culture" together with a new mode of consciousness, which would be a synthesis, and more than a synthesis, of the two with which we are acquainted.

Naturally, the argument is to a large extent speculative; but it is conducted with adequate knowledge, both of science and history, and with logical awareness. Mr. Davy believes that the gap between the old and the new culture is rapidly widening and that an entirely scientific culture may become so dominant that the values of the older culture would "survive only as eccentricities". The evolution of consciousness so far has been manifested in the rise of the scientific culture which has been associated with a new mode, or focus, of consciousness. The names chosen by the author for the two consciousnesses are sufficiently indicative of their nature—the 'participating' and the 'onlooker' consciousness. It is an important part of Mr. Davy's thesis that the scientific culture presupposes a consciousness which is aloof and distinct from the object, from 'nature'. The discussion of the gain and the loss which result from the transition to the onlooker consciousness is well worth attention.

There is no attempt to minimize the value or the inevitability of the scientific outlook; it is maintained, however, that there are other ways of knowing and experiencing which can display aspects of reality with which the scientific method cannot deal. The character of the third culture and the more comprehensive consciousness must remain largely conjectural, since they exist so far only in rare and eccentric individuals. Mr. Davy brings in here references to 'seers', which will disturb some readers; Rudolf Steiner is prominent among them. I hope that this part of the book will at least be read with respect, for it would be wrong to reject the 'seers' out of hand as victims of illusion. It must be owned, however, that their visions are incapable of verification and do not altogether cohere with one another. How far they indicate 'something beyond' the Nature studied by science is an open question. *Towards a Third Culture* is a stimulating book, of interest to all who are concerned about the nature of human intelligence and its probable future. Does consciousness evolve and, if so, how and whither? These are fascinating questions.

W. R. MATTHEWS

ORGANIZED THINKING AND EVOLUTION

The Nature of Life

By Prof. C. H. Waddington. Pp. 131. (London: George Allen and Unwin, Ltd., 1961.) 18*s*. net.

PROF. WADDINGTON is distinguished not only as a professional biologist but also as a leader of thought. In earlier centuries he would have been called a philosopher; but to-day's restriction of philosophy to logic, metaphysics or semantics forces him into the slightly pejorative category of 'thinker'.

In this short book he continues to illuminate our thinking about life, human as well as organic, in respect of its nature as a process, its methods of operation, and its results.

He begins by pointing out that science must always be concerned both with understanding and control, and that scientific theories which suggest new advances are often preferable to logically tidier, but less suggestive, theoretical models. He emphasizes the barrenness of 'nothing-but' views which vainly seek to explain complex results in terms of simpler origins, and proceeds to a useful discussion of the two main types of approach now prevalent in biology, which he calls "atomistic" and "continuum" theories, the one aiming at analysis of biological processes and structures into their ultimate components, the other at understanding them as wholes, operating through organized systems in which the parts are interrelated. Both are necessary; but over-emphasis on either leads nowhere. Elsewhere he uses the terms "substance" and "architecture" to characterize the two approaches: one might also suggest 'particulate' and 'organizational'.

He later points out that biological systems, from the genetic outfit to the cell, the individual, the population, and the ecological community, are all organizations with some capacity for self-regulation, and stresses the importance of unitary self-regulating fields and gradients in development.

He very usefully summarizes his own special contributions in this area. First, the realization that the process of development is genetically 'canalized' into a limited number of paths, each of them resistant to interference. For such genetically initiated and largely self-regulating systems of developmental change, he proposes the useful term *creode*, or "necessary pathway". Secondly, his discovery of *genetic assimilation*, whereby, through the operation of orthodox natural selection on genetic capacity to react to environmental modification, the Lamarckian inheritance of acquired character is simulated.

Both this pseudo-Lamarckian mechanism and that of creodic canalization involve cybernetic feed-back, and therefore cannot be adequately described in purely deterministic causal terms. In fact, 'arguing in a circle', or rather in a feed-back cycle, must be a feature of our new cybernetically based biological thinking. This applies also to evolution. At all levels there is a constant feed-back system operating between organism and environment, and between the past and the future direction of the course of evolution. As Waddington says, the implications of this fact are of enormous importance, but have scarcely begun to be studied or worked out.

Waddington proceeds to point out that the frequent assertion that biological evolution is based on chance is entirely untrue. 'Chance' events furnish its raw material, but the process itself is directional—self-steering, but automatically steering itself in a definite direction. This is because, in Ernst Mayr's phrase, natural selection is not a random but an 'ordering' mechanism. It is quasi-finalistic, or, to use Pittendrigh's useful term, 'teleonomic'—it orders chance events into directional channels.

As Waddington continues, "the most important of all the lessons to be learnt by man from the consideration of evolution arises, not from the methods by which evolution has been brought about, but from the nature of the results which it has achieved". The most important of these results is the achievement of progress. Are the later products of evolution on the average 'higher' than the earlier ? Are we, Waddington writes, "in any way better than the worms ? A short answer to this is similar to Dr. Johnson's answer to those who queried the reality of the external world. He kicked his foot against a stone. We might say we will take seriously the worm's claim to be our equals when the worms come and present it, but not before".

On the basis of an interesting analysis, Waddington concludes that we must assuredly recognize the existence of progress in evolution. But his analysis would have been more complete and his conclusion more firmly grounded if he had not equated biological progress with biological improvement. For one thing, his "we may expect natural selection always to effect an improvement" is too extreme—Darwin was both more comprehensive and accurate in the *Origin of Species* a century ago, when he wrote that natural selection inevitably leads to the improvement of the majority of organisms in relation to their conditions of life. In restricting the improvement to the majority of organisms he was presumably thinking of the inevitable limitations of all improvement. An improvement in a detailed adaptation such as cryptic resemblance cannot go beyond a certain degree of accuracy: an improvement in the efficiency of a way of life, such as that seen in the evolution of the horse, cannot proceed beyond a certain degree of specialization. All evolutionary trends tend to reach a limiting value and to become stabilized there.

Darwin's other caveat was inherent in his phrase "in relation to the conditions of their life". Biological improvement, in other words, is always relative. It may be relative to the efficacy of a single adaptation, such as Batesian mimicry; to life in an extremely narrow ecological niche, as with leaf-miners or clothes-moths; to specialization for a particular mode of life, such as grazing on open plains or internal parasitism or predation in the open sea; or finally to efficiency of general organization, as in mammals as against reptiles or teleosts as against other fish.

Progress may thus be broadly defined as improvement in general organization in relation to the entire evolutionary situation at that time, with the further proviso that it is itself progressive and does not bar the way to further improvement. We must therefore distinguish between 'improvement', which is general and indeed universal, and the particular and very special occurrence of 'progress'.

The book ends with a short chapter on "Biology and Man", which rightly stresses the fact that the nature, mechanism and course of evolution change radically on its passage from its biological to its human or psychological phase. In this field again—as set forth more fully in his earlier book, *The Ethical Animal* [see *Nature*, **193**, 409; 1962], Waddington has made an important contribution, by pointing out that human behaviour and human ethics are based on what he calls authority-bearing or authority-acceptance systems in the human baby. In the present chapter he follows up this point by a discussion of free-will, self-awareness, 'unconscious' mind and other psychological matters in a somewhat tentative way.

In an earlier book, Waddington very properly took the physicists to task for neglecting to take mind and consciousness into account while yet claiming that physiochemical "explanations" of Nature were the best and most scientific. When he returns to this topic, as I am sure he will, I hope that he will focus his treatment on the central biological fact of psycho-physical unity, and on the most important of all progressive trends, the trend towards 'more mind', with the brain as the organ of improved awareness.

Meanwhile we are grateful to him for his clarification of many important factors in the all-important process of evolution. JULIAN HUXLEY

POETIC IMPRESSIONS OF A SCIENTIFIC ERA

The Poet and the Machine

By Dr. Paul Ginestier. Translated from the French by Martin B. Friedman. Pp. viii + 183. (Chapel Hill, N.C. : University of North Carolina Press; London : Oxford University Press, 1961.) 30*s*. net.

DR. PAUL GINESTIER is lecturer in French in the University of Hull. The theme which he is considering is an old one, and we may refer to the formulation of the problem by T. E. Hulme[1] nearly forty years ago: "The association of art and machinery suggests all kinds of problems. What will be the relation to the artist and the engineer ? At present the artist is merely receptive in regard to machinery. He passively admires, for example, the superb steel structures which form the skeleton of modern buildings, and whose gradual development in a parasitic covering of stone is one of the daily tragedies to be witnessed in London streets. Will the artist always remain passive, or will he take a more active part ? The working out of the relation between art and machinery can be observed in many curious ways. Besides the interest in machinery itself, you get the attempt to create in art, structures whose organization, such as it is, is very like that of machinery. . . ."

Dr. Ginestier makes several claims. He holds that imagery from the mechanical world is now being widely and effectively used in English, American and French poetry; from which he quotes freely and pertinently. The imagery he perceives as part of the archetypal patterns which emerge from the subconscious of Freudian man. There is thus a possibility of the re-vitalization of poetry, and an extension of its profound significance: "After the inhuman harshness of the industrial revolution which is coming to a close, the poets of the machine age are re-introducing the most profound and poetic humanism in a civilization in which we are beginning to lose hold because the speed of its progress made it lose touch with the realities of life" (p. 178). (At least two serious assumptions are latent in the quotation.)

So, he says, we must study the poetry of the machine: of fire, mine, forge, factory, building, bridges, traffic, harbours, motor-cars. The list of poets is formidable; it ranges from Villon, Milton, Musset (there is, curiously, no reference to Blake), Eliot, MacNeice, Carl Sandburg, E. E. Cummings, Hart Crane, Wallace Stevens; less familiar are the quotations from Cendrars, Emmanuel Aergeter, Ivan Goll, Loÿs Masson—and a host of others. The quotations, which are usually brief, are analysed in terms of standard Freudian imagery, with anthropological reinforcements. The outcome seems to be a kind of catharsis. "The poetry of the machine effects the transference of dreaming into the current of life, giving it a new value." Flight, for example, allows the poet to achieve "man's liberation from the Icarus complex, his feeling of being unable to effect 'the unification of the force which moves and the object which is moved'. Through the poetry of industrial effort, man will be able to recover from that psychopathology of failure which characterizes our age" (p. 175).

The author writes with great energy and conviction; the bulk of his reading and learning is enormous. His analysis is applied with great ingenuity, and sometimes with a certain *naïveté*; I might cite as examples the explication of the extract from Verhaeren, *Les Villes tentaculaires* (p. 57), or of Hugo's *La Conscience* (p. 84). Is it really valuable or valid to write (after quoting Ashley and Allard), "Thus the railway station has an obvious value for mental catharsis. One can dream about travelling or drop off into space without fear of being carried away. The freight train is one of the machine age's answers to man's fundamental need for a scapegoat [here there is a reference to *The Golden Bough*] but it has acquired an element of nightmare horror" ? (pp. 85–6).

For all Dr. Ginestier's enthusiasm and ingenuity, the central dichotomy seems to me still unresolved. What the poets have indeed done is extend the range of their imagery; they are probably using more contemporary idioms from the world of science than at any time since the seventeenth century. But the poet does not seem to have accepted the machine, integrated it into his poetic vision, any more than did the Romantics. Blake, Shelley, Carlyle, Morris revolted against the Age of the Machines for reasons that were predominantly social. The modern poet protests against the mechanical society as the destroyer of man's meaning as an individual. His fear is that of man as automaton—see Auden's *Epitaph to an Unknown Citizen*, or MacNeice's *Prayer before Birth*.

The quotations set out in the book suggest this protest, in varying degrees of bitterness, loneliness, frustration: and it is not enough to select examples of imagery, to point to their archetypal nature, and to conclude, merely because the imagery can be shown to have Freudian significance, that any poetic symbiosis has taken place. Before we can reach such a deduction each poem would have to be investigated as a whole, in the totality of its statement; and this the method of the book does not provide for. A mere study of the imagery, in isolated passages, is insufficient to establish the striking and optimistic claims which the author makes for the high destinies of poetry.

ORIGINAL THINKING IN SCIENCE

The Inspiration of Science

By Sir George Thomson. Pp. x + 150. (London: Oxford University Press, 1961.) 18*s*. net.

THIS small volume from the pen of a very outstanding British physicist is somewhat unique in many ways. The title corresponds reasonably well with the recurring theme of the author, who concerns himself, as a physicist, with the mode of action of scientists of great achievement. His thoughts on the manner in which they proceeded to establish their fame through their various works are sure to ring a responsive chord in the minds of those who have themselves given thought to the question of how the notable advances have come about. The author illustrates his views as to the reasons for success with many illuminating examples.

It is no easy task that is assumed in this work. The subject is not straightforward history of science (though there is a good deal of that inserted in the form of stories of the outstanding men of science) nor yet is it explored in text-book fashion, though here again the author pays enough attention to physics in particular to make his theme clear to those of limited knowledge. In my own case I had good cause to believe that Sir George succeeded very well in this second matter because I kept losing the volume until I found that one of my sons, fourteen years old, was removing it for his own perusal. Judging by his obvious enjoyment of the work there is every reason to conclude that the book should appeal to a wide audience, that many reasonably informed laymen, or students of the arts, should find it of considerable interest and value to them. Yet, even if it is judged from the point of view of the physicist, there is much of great value and, in my own case, the method of presentation of familiar matters was found to be most stimulating. To take one example, the discussion on Chapter 5 of mass, energy and matter is confined to less than eleven pages; but it concerns itself with a very fundamental subject indeed and the thinking of the author comes through admirably. This is surely something that should concern more and more scientists—the need to let others see how they think about the really important concepts of science, and no one could say that the author shirks this duty. One of the most educative processes in life is to be found in the opportunity to 'listen in', so to speak, to the thinking of acknowledged experts, an idea which lay behind the habit in the past of young scientists to attach themselves for a period to a school under some great man such as Rutherford. This method of learning is not so obviously followed to-day when the tendency is to go to a centre housing some expensive machine, not necessarily the home of a great thinker or thinkers. This may well be a fault in our present system. For this reason and many others, we must be grateful to the author for giving us so much of his own philosophy in his volume.

The book is a most welcome effort to explore an aspect of science as yet inadequately covered, and it can be highly recommended to professional scientists and to laymen who definitely wish to understand more of science and those who practise it. It could prove very attractive to senior school pupils in science who wish to acquire a clear picture of the breadth and depth of the fields ahead of them.

S. C. CURRAN

THE MIND OF THE CRIMINAL

The Psychology of Crime

By David Abrahamsen. Pp. xii + 358. (New York: Columbia University Press; London: Oxford University Press, 1960.) 48*s*. net.

AFTER his first comprehensive study, *Crime and the Human Mind* (New York, Columbia University Press; 1944), Dr. Abrahamsen offers in his recent book a reappraisal and critical assessment of the dynamics of criminal behaviour and, based on this, on the treatment of offenders and the prevention of crime. The book is an American counterpart of Edward Glover's *Roots of Crime* (Imago Publishing Co., London, 1959). It is one more contribution to criminology from the point of view of psychoanalysis, discussed in the light of the author's practical experience in the clinical examination of criminals and his research project on sexual offenders in the New York prison of Sing Sing.

Dr. Abrahamsen reaffirms certain fundamental results of dynamic psychology, the importance of experience in early childhood, the part played by emotional disturbance in the origins of a social and anti-social behaviour, and the significance of the unconscious for the explanation of apparently motiveless crimes. The psychoanalytical doctrine of the development of the child's mental life through different distinct stages offers an explanation of the manifest immaturity of many criminals as a regression, a fixation of an earlier stage, especially in the sexual sphere.

The multiple and relative character of crime causation is clearly seen with the infinite combinations of inclinations, environmental conditions and the degree of personal resistance. In the author's experience, emotional deprivation with its damaging effect on future personal relationships is a frequent cause of deviant behaviour. The latter may be either neurotic or criminal, an important distinction with regard to the origin and forms of manifestation and to the choice of treatment. As a forensic expert on insanity, Dr. Abrahamsen is, at the present state of our knowledge, reluctant to say in accordance with the Durham-doctrine whether a particular crime is the outcome of a specific mental disturbance. He rather prefers to interpret the McNaghten rules liberally; 'knowing' the wrongful character of one's act means not only intellectual perceiving, but also emotional understanding (p. 254). Prisons, though indispensable for secure segregation of dangerous criminals, are failures so far as treatment is concerned (p. 273). Only a detailed knowledge of the offender's character development from early childhood onwards and of the personal influences around him provides a reliable prognosis of persistent dangerousness, or susceptibility to treatment which should bring to the surface any positive traits on which something constructive could be built.

It is the merit of this book that it is not a mere collection of facts and figures but an interpretation of the empirical material. A psychoanalytical exploration of the unconscious relies on the interpretation by the examining psychiatrist. In an admirable chapter on the examination of offenders (p. 208 *seqq.*) the author rightly asserts that it requires intuition, if not art, to diagnose a human personality. At the same time, theoretical doctrines have to be adapted to the realities of present-day life. While traditional standards become unstable and relative, the treatment of deviant behaviour is less concerned with neurotic effects of suppression than with character disorders "reflecting a distorted ego and super-ego structure acting out" into crime (p. 64).

The lasting contribution of modern medical psychology to the study of crime is the insistence on intensive examinations of individual offenders. This is the keynote of the present book. Only when it comes to conclusions, certain generalizations and typified analytical conceptions are not always avoided. Guilt feeling is certainly often the basis of anxiety, but one likes to see more evidence of a craving for punishment as a frequent motivation of crime; the accident proneness of offenders may often be due to indifference, recklessness or, among certain personalities, to excessive day-dreaming. There are probably more and different motivations of shoplifting by women than the sexual interpretation offered by psychoanalysts. Perhaps the time will come when psychologists and sociologists join hands in a common effort to master the complex phenomena of crime.

M. GRÜNHUT

PLANNING FOR EXCELLENCE IN EDUCATION

The Year Book of Education, 1961

Concepts of Excellence in Education edited by Prof. George Z. F. Bereday and Prof. Joseph A. Lauwerys. Pp. x + 503. (London: Evans Brothers, Ltd., 1961. Published in association with the University of London Institute of Education, and Teachers College, Columbia University, New York.) 63*s*. net.

THE editors have chosen this year to concentrate on a field of study which is the scene of acute contemporary controversy. In doing so, they have performed a valuable public service, and if the *Year Book* suffers, as it always must, from the very varied degrees of excellence in its own contributions, it cannot be faulted in its main conception. America, Europe (including Britain) and the Soviet Block are all concerned to-day with concepts of excellence in education and with the practical question of how the education of those who excel should be planned. Debate on the subject has become heated, particularly in Britain, and this massive addition to our information should do something to weaken the force of arguments which are based on nothing but a combination of 'hunch' and ignorance. "It is really most astonishing", the general introduction points out, "that successes achieved in the U.S.S.R. with a common non-selective secondary school system should be used in Western European countries like Britain to justify the existence of a selective secondary system."

The first section of the book, which consists of a series of essays on different concepts of excellence, is the weakest. One gets, for example, an interesting account of the Yugoslav school system, a historical sketch of the development of American education, and a socio-economic essay on Asian society: but little about 'excellence'. It is unfortunate that the English contribution should repeat the legend of Arnold's responsibility for the cult of games as part of the education of the gentleman.

The second section is much more valuable and contains some excellent discussion of the different systems adopted to educate that aspirant after excellence, the 'gifted child'. Three main patterns emerge. The American and the Russian are firmly committed to the common secondary school, while the European and British show a tradition of segregated schools being modified in the direction of the 'comprehensive principle'. It is particularly interesting, for example, to read a classic exposition of the English 'tripartite' division by Lord James, immediately followed by a defence from Roger Gal of the French preference for postponing 'positive differentiation' until about the age of fourteen or fifteen. There are excellent descriptions of the Swiss and Italian segregated systems, but on the whole the major weight is given to the comprehensive schools of North America and the Soviet Block. This is probably justified if the editors are right in their feeling that the trend of world opinion is towards a common school with varying devices for differentiation within it, until the age of fifteen.

The device used to provide for the gifted child in the Soviet Block is the provision of a wide range of study circles outside school hours. These circles study mathematics, physics or languages in a more adult way and to a more advanced level than is provided for in the school curriculum. In North America the same objective is sought by the twin methods of 'enrichment' and 'acceleration'. The case studies in the third section of the book are mainly American and show that 'acceleration' is no more than the promotion by ability rather than age with which English public schools with a wide ability-range have long been familiar. Enrichment classes seem not unlike the Soviet study circles except that they find their place inside the curriculum instead of out.

A short review cannot do detailed justice to a *Year Book* containing forty-three separate articles, some, like Prof. Bereday's, of surely lasting value. But clearly no one ought to discuss the 'Grammar/Comprehensive' controversy further without referring to it. The proof reading has been at times curiously lax. It is startling, for example, to read that "the Muslims of Dacca were abolished to promote the cloth from Bradford and Manchester". A. D. C. PETERSON

ACTION AT A DISTANCE AND METAPHYSICS

Forces and Fields

The Concept of Action at a Distance in the History of Physics. By Dr. Mary B. Hesse. Pp. x+318. (Edinburgh and London: Thomas Nelson and Sons, Ltd., 1961.) 35*s*. net.

THIS book deals historically and philosophically with the concept of action at a distance up to its present almost complete eclipse by field theories. The scope is indicated by the headings of the eleven chapters, of roughly equal length: the logical status of theories, the primitive analogies, mechanism in Greek science, the Greek inheritance, the corpuscular philosophy, the theory of gravitation, action at a distance, the field theories, the theory of relativity, modern physics, the metaphysical framework of physics. There are two appendixes, a bibliography and indexes. It is a scholarly work, obviously the result of long study. The style is pleasant, but occasionally long sentences make the going heavy, for example, there are sentences of eight lines each on pp. 260 and 298. A reader unversed in the techniques of mathematical physics will find some of the book difficult. This is not due to proliferation of mathematical formulæ (there are few), but because, from the time of Newton, physics can scarcely be understood without its mathematical formulation. To those with the requisite background I recommend the book, particularly to young physicists who, by studying the queer ideas of their forebears, may come to see that they too may think queerly without knowing it.

However, in spite of the high merit of the book, the respect I have for the author's erudition, and the shrewd and penetrating remarks scattered through the pages, I ended it with some feeling of isolation. The party was on, I had been invited; but somehow I could not join in because I was wearing the wrong clothes. The thing was brought to a head in the closing paragraph of the book, which I now quote with the addition of my own italics:

"Our discussion has not enabled us to answer the question 'Do bodies act at a distance'—this in any case is not *the business of the philosophy of science*. It has not enabled us to show that physics itself gives a definite answer, because although we have maintained that physical theories are asserted as facts, the problem of action at a distance is not so much a problem of particular theories as of *metaphysical framework*. The discussion has, however, enabled us to compose some variations on a theme: namely, the historical, heuristic, and logical importance for physics of ideas and assumptions commonly called *metaphysical*. A society which is uninterested in *metaphysics* will have no theoretical science."

Reading this over, particularly the italicized parts, I oscillate between extremes of humility and arrogance. Dr. Hesse handles with assurance certain technical expressions which I do not understand, and modesty demands that I creep into a corner, leaving her to pontificate in her field of expertise. But, on the other hand, I am a theoretical scientist, and I begin to wonder whether my inability to understand what she says about theoretical science may not be due to the absence of meaning in her words. In this mood, I feel inclined to throw them back at her, telling her that the philosophy of science and metaphysics are nothing but two empty battered tin cans drawn behind the triumphal car of science on strings two or three centuries long. It would help me to find an equilibrium between these two extremes if Dr. Hesse would look over my shoulder when I am trying to understand or solve some scientific problem, and say, as I write down one formula: "That is philosophical!" and, as I write down another: "That is metaphysical!" provided that in the circumstances self-consciousness did not prevent me from writing down any formulæ at all.

I searched the *Oxford English Dictionary* for a meaningful meaning of 'metaphysics', but did not find it; I found instead a quotation to end this review with: Shakespeare, *Taming of the Shrew*, I, i, 37 "The Mathematickes, and the Metaphysickes, Fall to them as you finde your stomacke serves you".

J. L. SYNGE

THE COSMOLOGICAL PROBLEM

Fact and Theory in Cosmology

By Prof. G. C. McVittie. (A Survey of Astronomy, Vol. 3.) Pp. 190. (London: Eyre and Spottiswoode (Publishers), Ltd., 1961.) 15*s*. net.

PROF. McVITTIE, formerly of the University of London and since 1952 professor of astronomy in the University of Illinois at Urbana, is one of the leading authorities on the interpretation of the empirical data bearing on the cosmological problem. In his latest book, to quote his own words, he has attempted "to weld together the astronomical observations relevant to cosmology with cosmological theory without entering into detailed mathematical proofs". He is an unashamed empiricist in his outlook, and there is a refreshing air of 'realism' about his approach to a subject in which the inadequacy of the data tends to encourage dogmatic theorizing from intellectually seductive 'principles' and postulates. In his opening chapter on the nature of cosmology, he exposes the variant of the 'argument from ignorance' fallacy whereby it is asserted that a statement is to be taken seriously if no observational evidence 'against' it can be adduced. Nevertheless, although McVittie lays his emphasis on the empirical data, he recognizes the necessity of theory for their interpretation.

Chapter 2 is devoted to an introductory account of the fundamental problem of distance determination, including a careful description of the use of Cepheid variables to determine distance moduli of local galaxies. Prof. McVittie brings out very clearly the uncertainty in our knowledge of the distance of so familiar an object as the great nebula in Andromeda. Chapter 3 is on the galaxies in general, and is useful for bringing together both visual and radio astronomy.

The next chapter, on theories of the universe and links with observation, is followed by one in which the effects of the red-shift are described, in particular its relation to distance. McVittie emphasizes that this relation is, in general, non-linear and that the linear form holds only for small shifts.

In Chapter 6 we encounter the central problem of using the observational data to select a particular world-model. McVittie shows that the red-shift data are at present sufficient only to narrow the class of admissible models by restricting the range of possibilities for the expansion factor. To determine the space-curvature index, appeal must be made to estimates of the mean density of matter in the universe. The principal snag is that, unlike their red-shifts, the distances of remote galaxies can be determined only by prior choice of a model universe and cannot be assigned uniquely on the basis of the relevant empirical data (apparent magnitude determinations).

Hopes have been expressed in recent years that these obstacles might be by-passed by studying the distribution of class II radio sources. McVittie indicates the difficulties of this approach, and the restrictive assumptions underlying the belief of most radioastronomers that, if these sources are uniformly distributed in space, the law expressing their number as a function of limiting flux-density must involve the exponent $-3/2$.

The final chapters are devoted to the steady-state theory and to a brief summary in conclusion. There is an appendix of useful data relating to clusters of galaxies and references to literature.

The book can be warmly recommended as an authoritative introduction to the subject at a level intermediate between the popular essay and the advanced mathematical treatise. The print is very clear and the price is extremely reasonable.

G. J. WHITROW

A CONSERVATIVE VIEW OF THE PLANETS

Planets and Satellites

Edited by Gerard P. Kuiper and Barbara M. Middlehurst. (The Solar System, Vol. 3.) Pp. xx + 601 + 106 plates. (Chicago and London: University of Chicago Press, 1961.) 12.50 dollars; 100*s*.

THIS is the third of what was to have been a series of four volumes, now increased to five, dealing with members of the solar system. The first two, on the Sun and the Earth, respectively, are already well known. It must be at least ten years since Prof. Kuiper first planned the series, years during which the successful developments of rockets, artificial satellites and 'space probes', as scientific tools, have brought a revolution in the possibilities for research within the solar system. These developments have led naturally to a great revival of interest in important problems, comparatively neglected until recently, concerning the physical nature of our Moon and the planets.

The book, therefore, appears at a very opportune time. "Designed to be a reference book for the specialist and also a source of information for non-astronomical scientists working in allied fields of study" it gives a reliable picture of some of what we have learnt so far, starting from ground-based observations in both optical and radio frequencies. Some subjects of particular present-day interest have been reserved for Volume 4, including mapping of the lunar surface, planetary spectroscopy and comets. There is no discussion of what at present must necessarily be speculative theories, for example, of the origin of the planetary system. As mentioned in the preface, there has been some delay in publication, and evidence elsewhere shows that at least one or two articles were originally prepared more than five years ago, although with some later revision. However, this should not deter the reader; most of the subject-matter is of the less-ephemeral kind, and there is much which is not only of contemporary interest but also should remain valuable for many years. A good deal of the material appears here for the first time, while some has been available until now only in scattered publications.

S. Fritz and H. Wexler give a short, abundantly illustrated and very instructive article on photographs of the Earth from *Tiros I*. Clyde W. Tombaugh describes the search for trans-Neptunian planets. One of the best chapters in the book is a critical review of the orbits and masses of planets and satellites, by Dirk Brouwer and G. M. Clemence. It is followed by a much more specialized article, by Y. Hagihara, on the difficult problem of the stability of the solar system. Rupert Wildt gives a clear, authoritative account of the theory of planetary interiors, a subject of much interest to physicists as well as astronomers. M. Minnaert, whose clarity of exposition is well known, deals with results from photometry of the Moon, and one of his sentences may perhaps be quoted: "Provisionally we are inclined to picture the lunar surface as very porous (photometric properties), all the details being covered by a thin layer of dust (polarimetry)". D. Barbier discusses the photometry of lunar eclipses, with special reference to properties of the Earth's upper atmosphere. Daniel L. Harris's chapter on the photometry and colorimetry of planets and satellites contains many hitherto unpublished measurements, made at the McDonald Observatory. There are two particularly good contributions by Audouin Dollfus, the first on polarization studies, the second on visual and photographic studies of planets at the Pic du Midi, which should lead to a wider appreciation of our debt to the author and his mentor, Bernard Lyot, who have greatly influenced present ideas about planetary surfaces and atmospheres. Edison Pettit describes early thermocouple measurements of planetary temperatures, and is followed by William H. Sinton on more recent radiometric work.

There are three chapters on radioastronomy. In the first, Cornell H. Mayer describes radio measurements in general, especially as they relate to thermal emission. Perhaps the most interesting result, now well known, is the high temperature, about 600° K., shown by Venus at 10-cm. wave-length. The next two chapters, which might have been combined, are by B. F. Burke and Roger M. Gallet, respectively, both dealing with the intense bursts of radio emission from Jupiter, not yet fully understood. Milton L. Humason contributes a selection of planetary photographs taken with the 200-in. telescope and W. S. Finsen some interesting colour photographs of Mars. Although the illustrations are very good, I have the impression that there has been a perceptible loss of quality, probably unavoidable, in reproductions of planet photographs here and elsewhere in the book. The final chapter is by the senior editor, who winds up with an account of searches for intra-Mercurial planets and for new satellites.

The book is to be welcomed as a valuable addition to the rather sparse literature of this corner of astronomy. As in most collective works of this kind the articles do not appear to be all equally valuable, but their general standard is very satisfactory; half a dozen of them impressed me as unusually good. Editorial policy appears to have been to avoid subjects or theories which are pretty certain to change rapidly in the next few years. This may not suit the taste of some readers, but it ensures a longer useful life for the book.

R. O. Redman

THE EARTH TODAY

The Earth Today

Edited by A. H. Cook and T. F. Gaskell. (A collection of papers dedicated to Sir Harold Jeffreys by some of his students and colleagues on the occasion of his 70th birthday.) Pp. xi+404. (London: Royal Astronomical Society, 1961. Distributed by Oliver and Boyd, Ltd.). 80*s*. net.

It was a happy idea of the Royal Astronomical Society to arrange a special issue of the *Geophysical Journal*, also available as a bound volume, containing papers by pupils and colleagues of Sir Harold Jeffreys in celebration of his seventieth birthday. The title appropriately recalls the four editions of Sir Harold's great work *The Earth*, which is a landmark in the application of mathematical methods to the solid Earth. The papers are restricted to those on subjects which Sir Harold discusses in *The Earth* and therefore reflect the influence of his ideas. The first group of papers discusses the motion of satellites around the Earth and the consequent determination of the Earth's external gravitational field from observations of them. The next two groups deal with seismic body and surface waves. The fourth with the free oscillations of the Earth, the fifth with problems of heat conduction in the Earth. The two articles on the theory of the excitation of the Eulerian nutation and the Cromwell equatorial current and two on instruments complete the volume.

The volume, perhaps appropriately, respects Sir Harold's views on 'the Earth to-day'. Our planet is presented as being a perfectly elastic body, entirely non-magnetic, no drift of continents is allowable, and of course no convection in the mantle—silence hanging over the recent apostasy of oceanographers on the latter topic. Even Sir Edward Bullard, discussing heat-flow through the Atlantic Ocean, only hints at convection in the mantle. To maintain this static view of the Earth it is necessary to ignore some very important experimental results, and following Sir Harold's example in the fourth edition of *The Earth*, where the subject of palæomagnetism is refuted in two self-contradictory paragraphs, F. F. Evison explains away the rock magnetism data by a hypothesis which any field geologist could as simply refute as Dr. Samuel Johnson's famous rebuttal of Berkeley's philosophy. Or perhaps these critics of continental drift are believers who are following the precepts laid down by Cornfor in *Micro-Cosmographica Academica*, that ancient guide to academic politics, which advised those who wish to get new ideas accepted to argue weakly against their own side.

One may conclude, therefore, that while all geophysicists will wish to possess this valuable book, it would be a pity if anyone thought that it was in any real sense a survey of the growing points in geophysics to-day. Yet the subject has now reached a stage where it seems that the exciting hypotheses that the Earth has formed by accretion, the continents have drifted, the ocean floor has recently been formed and thermal convection is occurring in the mantle, can all be finally checked by new experimental methods.

S. K. Runcorn

EARLY MODELS OF THE UNIVERSE

The Astronomical Works of Thabit B. Qurra

By Francis J. Carmody. Pp. 262. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1960.) 48*s*. net.

Dr. Carmody's book is the first comprehensive collection that has ever been available to Western scholars of the works of the Arab astronomer Thabit ben Qurra. The work is not a translation; the author has reproduced principally, but not exclusively, the texts of Gerard of Cremona (1114–87), to whom we must always be indebted for the translation into mediæval Latin of much of the Arabic corpus of astronomy.

Thabit ben Qurra (Bencorath) was born about A.D. 836 at Harrân in Upper Mesopotamia. He became the leading member of a group of four translators who, following the enlightened practice established by al-Ma'mûn, Caliph of Baghdad A.D. 813–33, continued the translation of the Greek astronomical manuscripts into Arabic. His predecessor, al-Hajjâj, had translated the Almagest. Thabit had used the work of al-Hajjâj and realized that there were errors in some of Ptolemy's basic data. He tried to lessen the error by using a tropical reference for the Sun which did not neglect the apparent precession of the stars. To this end he wrote his two most important works, *De Anno Solis* and *De Motu octaue spere*. In the former he quotes Ptolemy's statement that the difference between the two types of solar year—referred to fixed equinox position and referred to star-positions—was negligible. Thabit endeavours to establish a method of reckoning the solar (anomalistic) year by making his reference point the solar apogee. Dr. Carmody has carefully checked all Thabit's calculations and has re-computed both forward and backward. By doing so he has revealed the reason for the rather indifferent results obtained by the Arab; for despite using carefully chosen parameters, Thabit has used a number of unjustified approximations.

In *De motu octaue spere* Thabit goes further into the problem of precession. He adopts the theory of trepidation—that the zodiac moves advancingly by about 8° and then retrogrades by the same amount, at the rate of about 1° in 80 years. Dr. Carmody gives two Latin versions of the work, and a very full analysis of the mathematical methods used, and also examples of the Toledan tables derived from Thabit's work. There follow three shorter papers, *De Hiis indigent expositione antequam legatur Almagesti*—"For those in need of an exposition before the Almagest is read"; in fact, for beginners or students. In the paper *De quantitatibus stellarum et planetarum et proportio terre* are some interesting contemporary ideas of planetary distances and dimensions.

The final work reproduced, in two parallel Latin versions, is *De Imaginibus*; a book of magic giving instructions for the making and burying of small images to increase one's chances of succeeding in various undertakings. Dr. Carmody finds Thabit's insistence on using astrology in connexion with the images strange; but as he states, Thabit was a Sabean. He was, in fact, a pseudo-Sabean, a Harrânian. The inhabitants of Harrân had been forced by the Caliph al-Ma'mûn, during the life-time of Thabit's parents, to adopt some recognized form of religion. They chose that of the Sabeans, a semi-Christian sect of Babylonia, tolerated by the Muslims, and mentioned in The Koran. Harrân was the provenance of that small group which had preserved since the time of Alexander the Great the Hellenistic and Babylonian cultures. The true Sabeans were star-worshippers versed in astrology and magic, and Sabeanism, at least as a cloak for their practices and beliefs, suited the Harrânians. Thabit was but one of many brilliant scholars and scientists from the same town who communicated a great deal of Greek and Babylonian knowledge to the Muslims.

In his valuable appendixes, Dr. Carmody gives a full account of his own critical method in preparing the book, and lists with meticulous care all his sources. He includes many clear diagrams, some extracts from the Arabic texts, and an analysis of many of the Arabic–Latin equivalents used by the early translators.

Dr. Carmody has not written for a popular market. This book is a further example, and an excellent one, of his devoted work in assisting present and future scholars in their research into the history of science.

Leonard W. Clarke

A CLASSIFICATION OF LIVING ANIMALS

A Classification of Living Animals

By Lord Rothschild. Pp. vii + 106. (London: Longmans Green and Co. Ltd., 1961.) 25*s*. net.

During his studies of spermatozoa, Lord Rothschild found that he was often frustrated by having to consult a number of books, instead of one, to find an up-to-date classification of the animal kingdom. It occurred to him that other scientists might have the same difficulty, and he has now produced a single-volume classification of living animals intended for "physiologists, biochemists, biophysicists and those biologists who are not familiar with the classification of animals". No extinct groups are mentioned, although occasionally members of such groups turn out not to be extinct at all, like the coelacanth and the mollusc *Neopilina*.

The author explains briefly the purpose of his book and how to use it. A summarized classification of the animal kingdom follows, together with the approximate number of described species in each group. A more detailed classification of living animals is given in Chapter 3, down to orders and sub-orders for all but the smallest phyla. Under the small phylum Entoprocta only families are given and under Sipunculoidea and one or two others only some genera are mentioned. These classifications have been discussed with specialists on each group or groups and should, therefore, be authoritative and up to date. The author admits, however, that he has not always taken the advice of the specialists, that any errors are his own responsibility, and requests that errors or misprints be pointed out to him when detected. Alternative classifications are given for three major groups, sponges, platyhelminths and nematodes, the preferred classification being given first in each case. (In the preferred classification of Parazoa (sponges), the order Calcarea has inadvertently been placed in the class Nuda instead of in the class Gelatinosa.) The Latin names of some "better known genera" are given throughout the text (Chapter 3) and additional examples are included in the index, together with the order or sub-order to which the genus belongs. A certain number of English vernacular names is also mentioned and some of these may be questioned by purists. Where an animal causes a disease which has an English name, it has been inserted after the generic name of the animal thus: *Plasmodium* (malaria).

The book and its index can be used to find out how the animal kingdom, or parts of it, are classified, which are the decapod crustaceans or the decapod molluscs, what are Rotifera and Squamata, etc. But they cannot necessarily provide answers to questions concerning the systematic positions of individual genera. A genus may be well known to one scientist and quite unknown to another, the choice of "better known" examples is bound therefore to be arbitrary. There seems to be a discrepancy concerning the number of generic names included, that given in the introduction being considerably higher than that implied in the publisher's note on the dust cover. But whichever it is, it represents a very small percentage of the estimated total number of known genera. If the limitations of the book are kept in mind, it should prove extremely useful to many others besides physiologists and biochemists. Parasitologists, for example, should find in it valuable information on the classification and systematic position of the hosts which harbour the parasites. As a work of reference it ought to find a place in all biological libraries, and many research workers will want to own a copy. May the author find that in this instance diligence is not without its reward.

ISABELLA GORDON

BIG GAME OF THE PLANT WORLD

Anatomy of the Monocotyledons

Vol. 2: Palmae. By Dr. P. B. Tomlinson. Edited by C. R. Metcalfe. Pp. xiii + 453 + 9 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1961.) 63*s*. net.

PALMS have for centuries stirred the imagination of dwellers in chilly temperate regions. They are among the most romantic of plants, conjuring up visions of moonlit Pacific islands and of ill-lit Victorian conservatories in the intervals between dances. For the botanist they have the added attraction of being among the least studied groups of flowering plants, largely because of their intractability in the herbarium. To make adequate specimens of the large palms requires a collector with the determination of Beccari, who pressed a whole inflorescence of *Amorphophallus titanum*. The identification of palms is thus no easy matter and any new evidence which helps to improve the existing imperfect classification must be more than usually welcome to taxonomists.

Dr. Tomlinson places both anatomists and taxonomists in his debt for the thoroughness and skill with which the large amount of original work contained in this volume has been carried out, as well as for the comprehensive survey of previous investigations which he gives.

The book is divided into two main sections, the first dealing with classification and the morphology and anatomy of the vegetative parts of palms, and the second describing in more detail the anatomical features of the genera which have been investigated.

The methods used in cutting sections of stems give some idea of the difficulties which faced Dr. Tomlinson and his predecessors; these include treatment with steam, soaking in hydrofluoric acid for weeks and even grinding thin sections, as with fossils. The leaves, however, are easier material for the anatomist, and, unlike the stems, show features of value in delimiting the groups which are here referred to sometimes as sub-families and sometimes as tribes. On the basis of these characters the elevation of "two groups formerly of minor taxonomic rank to the same status as the other main units" is recommended. A key, based mainly on leaf anatomy, is provided for the recognition of these 'groups'; it would have been easier to use if the trichotomies had been avoided, but it is an interesting example of the taxonomic uses of anatomy.

The other topics dealt with in Part 1 include germination and seedling morphology and the general morphology and anatomy of the stem, the leaf and the root. We are reminded of the sometimes enormous elongation of the cotyledon (up to 12 ft. in *Lodoicea*), of the great diversity of the juvenile leaves, and of the frequent occurrence of diffuse secondary growth in palm stems, among many other interesting and little-known features.

Part 2 follows in the main the plan of the previous volume in this series and provides a systematic account of the anatomical features of all genera so far investigated. There are numerous excellent illustrations, an extensive bibliography and indexes to authors and subjects.

Part 1 can be read with pleasure and profit by any botanist, Part 2 is more for the specialist in anatomy; the book should certainly be in every botanical library.

Dr. Tomlinson and Dr. Metcalfe are to be congratulated on an excellent volume which will still further whet the appetite for what is to come.

T. G. TUTIN

KEEPING SEEDS ALIVE

Seed Preservation and Longevity

By Dr. Lela V. Barton. (Plant Science Monographs.) Pp. xvii + 216 + 13 plates. (London: Leonard Hill (Books), Ltd.; New York: Interscience Publishers, Inc., 1961.) 50*s*. net.

IN 1948 Dr. Barton, in collaboration with W. Crocker, published *Twenty Years of Seed Research* (see *Nature*, 162, 594; 1948). The present book is to some extent an extension and amplification of the earlier one and reprints from it some graphs and plates, including the single plate in colour.

Some records of the survival or reputed survival of old seed are noted, and the interesting point is made that longevity of buried seeds is often longevity of moist or even fully imbibed seeds, and must depend on a dormancy differing from that which maintains viability under the low-moisture and low-temperature conditions which are experimentally favourable for survival.

A chapter is devoted to considering the effects of moisture on the life of seeds. Other external influences and internal factors affecting seed life are rather briefly reviewed. Subsequent chapters summarize work on the storage life of seeds of different types; vegetables, flowers, cereals, other crops, aquatic plants. Anyone engaged in the horticultural seed trade will be particularly interested in Chapter 11, concerned with the effect of different containers or packets on live seed storage.

Dr. Barton has come to acknowledge, a little grudgingly perhaps, the proved usefulness of chemical methods, in particular the now very widely used tetrazolium test, for determining rapidly the viability of some kinds of seed.

As data can obviously be classified according to either the species of seed concerned or the different factors influencing viability, a somewhat disconnected and patchwork arrangement results. Fortunately, a subject index and a separate author index do much to remedy this, although the indexing is not perfect. For example, no reference could be found to the quite important paragraph on the International Seed Testing Association and its rules. (Incidentally, the last published revision of these rules is based on the Oslo meeting of July 1959). Work on the duration of life in seeds and related storage conditions has been long continued, voluminous but scattered, and not only strictly experimental and scientific, but also commercial and merely observational. It is therefore not easy to write about it as a coherent whole. Moreover, Dr. Barton is careful to record objectively and generally refrain from criticism of the work of other investigators. Throughout the book the author's own critical appraisal of results reported, and suggestions for the integration of established facts, would have been very welcome.

The extensive, although of course still incomplete, bibliography is a most valuable part of the book. There is also a glossary for the non-botanical reader. *Seed Preservation and Longevity*, despite some limitations, brings together a tremendous amount of information and may remain for a long time the standard work of reference on its subject.

S. CLAY

TROPICAL FRESHWATER FISHERIES

Tropical Inland Fisheries

By Dr. C. F. Hickling. (Tropical Agriculture Series.) Pp. xvi + 287 + 68 plates. (London: Longmans Green and Co. Ltd., 1961.) 42*s*. 6*d*. net.

ALTHOUGH man has fished in tropical freshwaters for several thousand years it is only recently that he has taken a scientific interest in the subject. Indeed, twenty years ago this book would have been little more than a review article. As is clearly shown in the bibliography, the researches on which it is based had then only just begun. Of the 148 references cited, 18 were published before 1940, and most of the remainder appeared between 1950 and 1960.

A substantial part of the book's value lies in its intricate synthesis of diverse subjects and the clear statement of general principles which have emerged from this fast-evolving field. Its value is not, however, confined to biologists. If the pace of tropical fisheries research is to continue, the subject must have the sympathy and understanding of non-scientific administrators and politicians. For these purposes there could scarcely be a better advocate than Dr. Hickling. His style is enthusiastic and lucid, and the book is a well-balanced rendering of the numerous biological, technological, sociological and political factors that go to make up tropical inland fisheries.

The subject is treated in three broad divisions. First, there is a five-chapter account of the hydrological principles against which the biological factors and ultimately the fisheries themselves are reviewed. This section should be of particular value to students in tropical universities and to those with only a background of temperate climates. In a mere fifty-four pages we are given a clear account of hydrological conditions in rivers, lakes, dams and swamps. There is also a discussion of problems connected with sewage disposal, river pollution and swamp clearance. The diversity of conditions within tropical waters cannot fail to be impressive.

The biological factors of food supply, the condition of the water and of migrations are dealt with in the next three chapters. Here, too, Dr. Hickling gives a comprehensive introduction to a very complex subject, ranging from the anatomy of feeding mechanisms to an analysis of food chains and the interaction of the biological with the physico-chemical environment. Although this account reads smoothly and carries the reader across the boundaries of many subjects, no attempt is made to hide the unsolved problems which beset the fisheries biologist. Like the previous section, these chapters should serve as a good introduction for biology students within and without the tropics.

A chapter devoted to fishing methods, fish-preservation and marketing is a self-contained and fascinating essay. The fishing gear described includes both indigenous and imported kinds, and ranges from complex fishing machines like the 'day' of the Mekong River to what is surely the simplest known device, stirring up bottom mud and dissolved gases so as to asphyxiate the fishes.

The last seven chapters deal with the fisheries themselves and cover lake, swamp, river and flood-plain fisheries. One chapter is confined to the stocking of lakes and dams. These chapters could easily have been a dreary recital of comparative statistics, but they are far from being so. Indeed, it is in this part of the book that the first two sections are fully integrated with the main theme (a point which should show the importance of pure research to those politicians who sometimes consider it a dispensable luxury). Dr. Hickling takes a very broad view of his subject, and he is fully aware of the profound influence which social and political factors can have on the fisheries. To quote one example of these interactions, "... the construction of an all-weather road, to open up to a a reliable and lucrative market new areas of water, will do more to relieve fishing pressure on a non-migrant stock of fish than all the regulations at present applied, even assuming that these regulations were in fact enforceable at economic cost". No one can accuse Dr. Hickling of sheltering in an ivory tower. He has visited workers in the field and has directed a tropical fisheries research station for two years. This practical knowledge has clearly influenced much of what is written in these chapters.

Over-fishing is a hotly argued subject in the tropics, particularly among those concerned with fisheries in the major African lakes. Dr. Hickling takes a rather optimistic view of future developments, his optimism being based, as he says, on "the astonishing powers of recuperation of a tropical inland fishery". Certainly there are data which seem to support this point of view as applied to certain fisheries, principally those of the flood-plains and the impermanent Lake Rukwa But I believe that this optimism should be tempered so far as the fisheries of some lakes are concerned. In these waters, the conditions and the principal species are different, and above all, the fishery is continued throughout the year. Furthermore, although "recuperation" may describe the return of the fishery to economic levels in Lake Rukwa after partial desiccation, it does not describe the conditions obtaining in a relatively static lake. Perhaps 'resistance' would be a better word to cover the actions and reactions involved in the fishery of a permanent lake ? If the resistance is lowered, some form of strict control (as is imposed naturally in Lake Rukwa) may be necessary if the fishery is to recuperate; by then we have overfished and the economic consequences will be manifest.

Flood-plain fisheries obviously fascinate the author, and his detailed descriptions of their development and exploitation are of great interest since it seems inevitable that water conservation measures will eventually bring about their extinction. Here again is a subject which concerns both the biologist and the administrator.

There are a few minor taxonomic errors in the text and the outline drawings of fishes are weak (and sometimes incomplete). These are very minor blemishes in a book which must be considered as a major contribution to tropical hydrobiology and a most readable and important text-book in the field of fisheries research. P. H. GREENWOOD

THE MAMMALIAN EGG

The Mammalian Egg

By Dr. C. R. Austin. Pp. viii + 183. (Oxford: Blackwell Scientific Publications, Ltd., 1961.) 42*s*. net.

SINCE Dr. Pincus's monograph, "The Eggs of Mammals", appeared in 1936, considerable advances have been made in the study of the mammalian egg, which to-day is attracting the attention of an increasing number of workers. Consequently, a real need has developed for an up-to-date, authoritative treatise on this subject. This new book is, therefore, especially welcome. The author, Dr. Austin, is well known for his research work into the process of fertilization in mammals. His numerous papers published during the past decade provide the fabric on which the book is based.

To quote from the preface, "this book is an attempt to review in detail available information on mammalian eggs and to discuss briefly the trends of research from the point of view of the cytologist". It is divided into five main sections under the following headings: "General Biology of Eggs", "Structure and Function in Mammalian Eggs", "Cytoplasm", "Membranes and Investments", and "Manipulation of Eggs".

The processes of maturation, fertilization and cleavage are described in considerable detail, with special attention being directed to abnormal forms. This part of the book will prove especially interesting to those concerned with the study of early embryonic development. The reader becomes aware of many deficiencies in present knowledge; for example, the important phenomena of capacitation and fertilization *in vitro* are but poorly understood. Techniques described in the final section will assume considerable importance if egg transfer can be translated successfully from a laboratory research technique into a practical method of improving livestock.

The book is well illustrated with 76 text-figures, 17 of which are in full colour. However, it is debatable whether quite so many colour photographs should have been included, particularly in view of the cost of reproducing colour plates. Unfortunately, a number of the text figures appear out of sequence; for example, Fig. 46 follows directly after Fig. 39, while Fig. 40 is located some 23 pages later.

There is a most useful and commendably up-to-date bibliography, containing nearly 700 references, more than half of which date from 1950 onwards. The very high proportion of recent references gives a good indication of the present degree of activity in this field. In addition to a subject index, there is a complete index of organisms referred to in the text. Two appendixes, one on egg transfer and the other on culture of eggs *in vitro*, contain in summarized form the main details of relevant papers with references. Attention is directed to two errors in Appendix 1: on p. 125, "Belgian Hare" is classified as a species, whereas it is a breed of rabbit, and on p. 141, it is stated that Hunter, Adams and Rowson (1954) transferred "unfertilized eggs to ewes which were then mated". They did, in fact, transfer fertilized eggs to ewes which had been mated previously with vasectomized rams.

Although relatively expensive, few reproductive physiologists can afford not to have such a useful reference close at hand, while the general biologist will also find in it much of interest. The whole book is very well produced. C. E. ADAMS

WHAT PROGRESS IN RADIOBIOLOGY?

Mechanisms in Radiobiology

Edited by Maurice Errera and Arne Forrsberg. Vol. 1: General Principles. Pp. xv + 534. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1961.) 16 dollars.

Studies on Quantitative Radiation Biology

By Prof. K. G. Zimmer. Translated by H. D. Griffith. Pp. 124. (Edinburgh and London: Oliver and Boyd, Ltd., 1961.) 15*s*. net.

Radiobiology

Proceedings of the Third Australian Conference on Radiobiology, held at the University, Sydney, 15–18 August, 1960, by the Australian Radiation Society. Edited by P. L. T. Ilbery. Pp. xi + 314. (London: Butterworth and Co. (Publishers), Ltd., 1961.) 63*s*.

Progress in Photobiology

Proceedings of the Third International Congress on Photobiology, Copenhagen, 1960. Edited by B. Chr. Christensen and B. Buchmann. Pp. xv + 628. (Amsterdam: Elsevier Publishing Co., Inc.; London: D. Van Nostrand Company, Ltd., 1961.) 126*s*.

THE first of the works listed above attempts (in its two volumes) a general review of radiobiology and may be taken as an occasion for some general comments on the state of this subject. As the second volume on multicellular organisms appeared first (and has already been reviewed—*Nature*, 190, 72; 1961) it is possible in assessing the subject-matter to take this into account. The earlier chapters of the first volume deal with: (1) the physical principles of ionizing radiations; (2) the radiation chemistry of water and simple organic and inorganic solutions; (3) the action of radiations on certain biological macromolecules, isolated and *in situ*. This is followed by chapters on various biochemical processes, on various cytological effects including replication, on radiation genetics and the use of radiations in plant breeding. The last two chapters would have been more happily placed in Volume 2, while Eldjarn's and Pihl's article in Volume 2 on the mechanisms of protective and sensitizing action really belongs to Volume 1.

The authors of the articles in this volume have produced a valuable guide to much of the literature of their subjects. From a study of these articles it will be evident that the subjects considered are at very different stages of development. The radiation chemistry of simple solutions is relatively advanced, and a good deal has been learnt about the effects of radiation on biological macromolecules, such as proteins and nucleic acids. Hutchinson and Pollard's chapter on the latter concentrates on the 'target theory' aspects, largely ignoring the fairly extensive knowledge of chemical changes produced, which are, however, considered to some extent by T. Alper under "Sub-cellular Units".

However, a study of the later chapters shows that there is a large gap to be filled between the knowledge of the actions of the radiations on biological substances and the consequent effects on the life of the cell. Notwithstanding an enormous amount of experimentation, largely supported by the various atomic energy authorities, very little has been certainly established about the mechanisms of these effects.

There is, of course, a great deal of information about the overall effects of radiations, for example, lethal action, genetic effects, effects of oxygen, specific effects in certain organs such as bone marrow, but knowledge of the essential origin of these effects seems to have progressed very little in the past ten years. It is still impossible to say which is the sensitive site (or sites), why some cells are much more sensitive than others; which of the innumerable biochemical effects are important and primary, and which secondary. There is a very good reason for this *impasse*—until the main biochemical processes involved in living cells and how they are co-ordinated with each other are known at least in outline, it is unlikely that we can pin-point the effect of the perturbations caused by ionizations. This stage has not been reached. Even in the case of chromosomal replication and synthesis of deoxyribonucleic acid which have long been thought to be sensitive processes, little is known of the critical step or steps at which radiations act; but this is not surprising as the sequence of reactions involved is only now being unravelled. A study of the relevant chapters will, I think, show that many researches have been undertaken on the basis of a purely temporary conception of the importance of one process or another. It could not be asserted that no useful knowledge is obtained in this way, but it has to a great extent been unfruitful. It seems a pity that these very considerable efforts could not have been applied to the examination of normal functioning of cells as a necessary basis for a non-empirical radiobiology which must eventually find its expression in biochemical terms.

The other volumes listed above are more limited in their scope. Prof. Zimmer's is of a more physical character and for the most part is an up-to-date and critical assessment of 'target theory'. The final chapter describes micro-wave techniques for identifying transient radicals, which have demonstrated that in dry or semi-dry systems, such as seeds, free radicals formed under the action of radiations persist for appreciable times; but although the radicals giving signals can be identified in the case of some pure substances, identification in biological material is very uncertain and may remain so in view of the vast variety of substances present.

The third volume consists of papers contributed to a conference on radiobiology in Australia. Although these cover a wide range, it is difficult to trace any connected theme running through them —in fact, the volume is a collection of papers on a variety of topics, some being in the nature of reviews and others apparently original papers. Compilations of this kind have a rather limited usefulness since the reviews often repeat those given elsewhere and the original papers would be easier to find in some recognized journal. Indeed, one cannot help but think that in this subject far too many records of conferences are being published. There have been occasions when the papers given at a conference provide a useful summary of recent work, but this is doubtfully so in the present case.

The last volume listed is in a rather different category. It does cover comprehensively most of the lines of photobiological research which are being pursued at the present time. Although much of the work recorded is to be found in the literature elsewhere, it is undoubtedly valuable to have all these fairly brief statements of results, which together give an excellent bird's-eye view of the subject, collected in one volume. J. A. V. BUTLER

MODERN AEROBIOLOGY

The Microbiology of the Atmosphere

By Dr. P. H. Gregory. (Plant Science Monographs.) Pp. xv+251+7 plates. (London: Leonard Hill (Books), Ltd.; New York: Interscience Publishers, Inc., 1961.) 60*s*. net.

THE microbiology of the air is a subject of interest to workers in such diverse fields as phytopathology, palynology and the study of allergy, and this intellectually satisfying and exhaustive treatment of the subject will, therefore, be greatly welcome. Aerobiology is no new subject. It throve in the latter half of the past century. In evidence of this it is only necessary to recall Pasteur's *Mémoire sur les corpuscles organisés qui existent dans l'atmosphère* (1861) and Miquel's long book *Les organismes vivantes de l'atmosphère* (1883). However, the subject then languished, to be revivified in recent decades. Through Dr. Gregory's own researches, and through those he has inspired, the quantitative study of the composition and movement of the air-spora (composed of such varied elements as bacteria, algae, yeasts, spores of fungi mosses and ferns, pollens of plants and cysts of protozoa) has made spectacular progress in the post-war years. In this progress the development of a satisfactory mathematical theory of the dispersal of spores in turbulent air, and the invention of suitable techniques (notably the Hirst spore-trap) for accurate quantitative sampling of the spore load of the atmosphere, have played decisive parts.

The subject is presented in a most logical manner. After a full historical introduction, the atmosphere is considered as the medium in which the aerial plankton or spora is suspended. Then problems of 'take-off' of fungal spores and of other elements of the spora are briefly reviewed, followed by a consideration of the horizontal eddy-diffusion of the spore cloud. Some of the older biologists, including myself, may find the derivation of the formulæ somewhat difficult; but the author does his best to make the mathematical argument as painless as possible. Deposition of spores is fully considered both under the controlled conditions of a wind-tunnel and in Nature. Then techniques of sampling the spora are critically evaluated. A detailed account is given of the composition of the air spora near the Earth's surface, in the upper air, and indoors. Deposition of spores is fully considered and the difficult mathematical treatment of deposition gradients is explored in detail. The controversial subject of long-distance dispersal of pathogenic fungi is presented clearly and without bias. The book ends with the author looking outwards from our planet: "After exploring the stratosphere, we shall then be better able to tackle outer Space. Time is short; before we know where we are, we shall have the Moon at our doorstep and Mars and Venus on our hands".

There can be little doubt that this book is a landmark in biology, and it required a man with a mathematical outlook, with the gift of experimental ingenuity and with imaginative insight to achieve this fine synthesis.

The book is well and clearly written and beautifully produced—perhaps too beautifully. There are four pleasing coloured plates of air-spora painted by Miss Bunce. They add to the general attractiveness of the book without, perhaps, contributing much to its scientific value. Line drawings would have been nearly as effective and surely a black-and-white diagram might, with positive advantage, have replaced the half-tone plate of the capillary impinger. All libraries with an interest in botany, medicine or plant pathology will want to have this book, but all too few individuals will be able to afford it.

C. T. INGOLD

THE MONOGENETIC TREMATODES: A RUSSIAN VIEW

Monogenetic Trematodes

Their Systematics and Phylogeny. By Boris E. Bychowsky. Edited by William J. Hargis, Jr. Translated from the Russian by Pierre C. Oustinoff. Pp. xx+627. (Washington, D.C.: American Institute of Biological Sciences, 1961.) 10 dollars.

THIS formidable monograph on the monogenetic trematodes was completed in 1955 and first published in Russian in 1957. It represents a comprehensive study with 115 Russian and 235 other citations from the original literature on the subject, but some important papers were not consulted by the author and others were known to him only by abstracts, so that the book is neither up to date nor fully documented. The author's attitude is dogmatic, his treatment of the subject is pedantic and the style of his writing is seldom lucid. The reader is irritated by imperious statements and wearied by verbosity, and he senses most acutely the harrowing enormity of the task which occupied editor, translator and several other persons for 30 months.

The book is divided into three parts, each of which has several chapters. Part 1 is concerned with morphology, biology, embryology and life-cycles, and there is a supplement on matters of a developmental nature. There is much information here which did not emanate from the U.S.S.R., and also 260 out of a total of 315 illustrations—line diagrams without annotations. The treatment of structural detail adds very little to what was known already, but the Russian feeling for ecological matters is evident in the chapters dealing with biology and life-cycles. The monogenetic life-cycle is often regarded as simple, but when the succession of forms which arise during the different seasons of the year is considered in relation to cyclical changes in the life-cycle of the host and the interplay of variable environmental factors there is added complexity which is informative. This is especially true when the host is a migratory fish dividing its activities between some river or the littoral zone and the open sea.

Part 2 of the book is concerned with the occurrence of monogenetic trematodes on their hosts and with the analysis of what is generally called specificity. Bychowsky is commendably cautious about the use of this term 'specificity', which he defines as "a potential aptitude for determined relations with the host, or, in other words, the ability to exist on this host" (p. 326). He prefers to consider the 'occurrence' of the parasite, that is, the 'realization' of its possibilities of existence on a given host under conditions which are determined by ecological factors. Much information from the original literature is collated here in various ways. Of the 958 known species of the Monogenea, 806 (84·1 per cent) occur on species of fishes belonging to a single genus and only 152 (15·9 per cent) on fishes belonging to more than one genus. Of the grand total, 903 species occur on host genera belonging to a single family and only 55 species on host genera belonging to more than one family, more than two-thirds of these occurring, however, on fishes belonging to a single order. There are 154 genera of Monogenea which infest fishes and 95 of them are found each on a single family of hosts only, and of these 67 are monotypic genera and 28 are genera usually having 2–6 species (three exceptions with 10, 13 and 23 genera). These and other analyses lose some of their value, however, because the author does not utilize "a certain amount of data" (p. 240) and "faulty or doubtful data" (p. 280). Another drawback is that specific and other diagnoses are taken at their face value. Any future evaluations of degrees of specificity will call for careful consideration of possible errors of diagnosis.

Part 3 of the book is concerned with systematics and phylogeny. Bychowsky here exposes himself to adverse criticism. He would promote the order Monogenea to the status of a class (which also involves raising the status of the Digenea) and would change the name to Monogenoidea because "the contemporary data on morphology, development and life-cycle of these groups do not provide any basis to suppose the commonness of their origin", and because "similarity in structure . . . is a purely converging phenomenon which does not in any way indicate their actual phylogenetic consanguinity" (p. 563). The Monogenea, we are told, had a more recent origin than the Digenea by an ancestral line of Turbellaria from which the Cestoda also arose. The Udonellidae is removed from the Monogenea because "this group descended from Turbellaria quite independently" and because the larva is not "equipped with a cercomere and its chitinous armature" (p. 570). The Microbothriidae is threatened with removal from the Monogenea for a similar reason (p. 463). Other readers may also consider that Bychowsky attaches too much importance to the hooklets of larvæ. At first sight, his taxonomic scheme has an alien look, but when it is compared with the scheme it is intended to replace there are many common features, although the unit of super-family is discarded. There are 29 families: 16 of them already existed, 11 are promotions from the status of sub-family, and only 2 are new, and these have only one genus each. The "Monogenoidea" is divided into 2 sub-classes, the Polyonchoinea (with 3 orders and 17 families) and the Oligonchoinea (with 3 orders and 12 families). There is some ambiguity in the delineation of these groups. The Polyonchoinea are defined as forms having 12–16 marginal hooklets (p. 405), the Oligonchoinea as forms having only 10 (p. 481), so that the prefixes to these names are misleading. The sub-classes are derived from two types of larvæ which are said to have 14–16 marginal hooklets and 10–12 marginal hooklets respectively (pp. 100–101), the line of demarcation between the two groups now becoming arbitrary. Hooklets are not mentioned in the diagnoses of families of Oligonchoinea, but the statement about 10 marginal hooklets is repeated for the largest order of this sub-family, the Mazocraeidea (p. 498). However, for some families of this order the full complement of marginal hooklets cannot be determined, because the larvæ develop precociously and emerge from the egg with an imperfect complement of hooklets and with some of the haptorial accessories of the adult already formed. This is true of Microcotylidae and Discocotylidae. Other families of the order contain forms with 6 pairs of larval hooklets which must be considered marginal and it is not legitimate to discount any of them on account of size. In *Octostoma scombir* (Mazocraeidae) the lengths of hooklets of the first 5 pairs "fluctuate around 0·02 mm." and the length of the hooklets of the sixth pair is "about 0·022 mm." (p. 215), and in *Diclidophora luscae* (Diclidophoridae) the comparable lengths are 0·025 mm. and 0·028 mm. respectively (p. 218).

To say the least, Bychowsky's taxonomic system is built on weak foundations. We shall need to know much more about larval hooks and hooklets and especially about the relationships between them—which can be revealed only by a study of the formative processes during development—before we can erect a reliable system of classification which is based on their numbers and their various arrangements. The Russian system has produced some oddities. The names of Odhner's sub-orders Monopisthocotylea and Polyopisthocotylea, which have a wealth of meaning for students of the monogenetic trematodes, have been restricted to sub-orders within the Polyonchoinea. The well-known genera *Gyrodactylus* and *Polystoma*, which are parasites of cyprinid fishes and Amphibia respectively, are both placed in the order Gyrodactylidea. These are specialized types, *Gyrodactylus* in respect of viviparity and *Polystoma* in respect of structural complexity. Each has 16 marginal hooklets arranged as 8 pairs, but this is an adult character of the former genus and a larval character of the latter genus.

BEN DAWES

NEMATODES OF PLANTS

Principles of Nematology

By Prof. Gerald Thorne. (McGraw-Hill Publications in the Agricultural Sciences.) Pp. xiv + 553. (New York: McGraw-Hill Book Company, Inc.; London: McGraw-Hill Publishing Company, Ltd., 1961.) 116*s*. 6*d*.

THE first thing to be said about this book, which is in some ways admirable, is that its title is extremely misleading. Far from dealing with nematodes as a whole, it is devoted almost exclusively to those which are parasitic in plants with a few representative free-living, soil-inhabiting species. In fact (p. 91), representatives of only seven out of thirty-one superfamilies of Nematoda recognized by B. G. Chitwood (1959, no reference in bibliography) are mentioned. Free-living freshwater and marine nematodes and those parasitic in animals are only referred to very briefly in passing. A comprehensive treatment of the phylum Nematoda as a whole would have expanded the book beyond the limited aims defined in the introduction. Nevertheless, the appropriation of the term 'nematology' is unfortunate. If this term means anything, it implies the study and knowledge of the whole group and not just an arbitrarily selected part. Entomology includes both butterflies and fleas and no one would wish it otherwise. It is also disturbing to read on p. 82 the words "Nematology, like entomology, zoology and other branches of biological science. . . .". Nematology is *part* of zoology, not equivalent to it. Prof. Thorne is not the only specialist to commit the sin of equating his own speciality to the whole of the subject of which it is a part, but it is none the less unfortunate.

Apart from these comments the book is a valuable contribution. The first chapter begins with an interesting historical introduction illustrated by photographs of distinguished workers in the particular field of nematology with which the book deals. This is followed by short discussions on the importance of nematodes to agriculture, methods of control, including a short section on soil fumigation and useful suggestions for the training of nematologists. Chapter 2 is concerned with collection of material and estimates of population density, which, as the author points out, are "subject to great error". In Chapter 3 great emphasis is laid on the thorough training of nematologists in microscopic techniques and the use of first-class optical equipment essential for the study of the small and often elusive details necessary for the identification of these difficult animals. There are useful sections on fixation, dehydration and the preparation of "whole mounts" as well as on identification and the description of new species. In connexion with the last-mentioned aspect the author makes the refreshing comment "Select short, easily pronounced names. A name does not have to be descriptive of the organism although it is desirable that it be so when feasible. It is far better to draw from four to six letters at random and arrange them into a pronounceable barbaric name than to create a jaw-breaking monstrosity". It may be anathema to the purists but how much one recalls Leach, who, in the last century, created quite euphonious names for genera of isopod Crustacea such as *Conilera*, *Lonicera*, *Cirolana*, *Anilocra* and so on, all anagrams or near-anagrams of the name Caroline.

The rest, and the major part of the book, 400-odd pages, is devoted to a systematic account of soil nematodes most of which are, or are suspected of being, harmful to crops but also including some saprozoic, bacteria-feeding and predacious species. This is, for the systematist and 'practical' man, the most important part of the book. The descriptions are clear and succinct and the illustrations numerous and good. In the case of species of proved economic importance good accounts are given of the damage caused, host plants, distribution and methods of control.

This book is the production of a systematist, with, as would be expected, a strong bias towards the *ad hoc* methods of control. He displays little awareness of modern work and methods of approach to the nematode problem or to the physiology of these important animals. The word 'principle' has been much abused in many books, but there are here only methods, no principles as I understand the term. Nevertheless, this is, within its limits, a useful and much-needed book, and is therefore sincerely welcomed. It is very well produced and I have noticed no printing errors. A. D. HOBSON

TOXICOLOGY OF AROMATIC HYDROCARBONS

Toxicology and Biochemistry of Aromatic Hydrocarbons

By Dr. Horace W. Gerarde. (Elsevier Monographs on Toxic Agents.) Pp. xiii + 329. (Amsterdam: Elsevier Publishing Co., Inc.; London: D. Van Nostrand Company, Ltd., 1960.) 30*s*.

THIS useful monograph consists of two parts. Part 1 is devoted to a general treatment and includes nomenclature, sources, analysis, toxicology and biochemistry of aromatic hydrocarbons as well as a chapter on the treatment of exposure to these compounds. Part 2 deals, in handbook style, with twenty aromatic hydrocarbons of industrial importance. These include benzene, the mono-, di- and poly-alkylbenzenes, and di-, tri- and poly-cyclic aromatic hydrocarbons. Each compound is classified in a similar manner to Part 1 and given brief treatment. A chapter on solvents, fuels and lubricants, and a glossary of terminology are also included.

To the analytical toxicologist, the outstanding feature of this book is the omission of any mention of vapour-phase chromatography. On page 87, Dr. Gerarde states that "If sufficiently sensitive methods of analysis were available, breath analysis could serve as a test for exposure to these hydrocarbons . . .".

One is of the opinion that, by a combination of vapour-phase chromatography and infra-red spectrophotometry, sufficiently sensitive methods are in fact available. Perhaps, too, application of such techniques might eliminate the need to wait for the appearance of leucopenia or thrombocytopenia as evidence of exposure to hydrocarbons; the 'biochemical lesion' may thus be prevented from occurring. One might pertinently enlarge the discussion here and say that, in Great Britain at least, there is a great need for the establishment of a centre for research into toxicological analysis and for the provision of a routine service for the practical application of the fruits of such research. This would be one way, at least, of solving one of the problems posed in Dr. Gerarde's statement on page 87, that "The accidental ingestion of chemicals is an infrequent occurrence in industry but regrettably too common in the home".

Chapter 4 contains one or two blemishes. For example, on page 38 reference is made to ". . . benzene and its more volatile homologues . . .". This statement is ambiguous; it suggests that the homologues of benzene are more volatile than benzene itself. This, of course, is inconsistent with the statement on page 26 that ". . . progressive decrease in volatility with increasing molecular weight accompanies the lengthening of the alkyl chain".

The sentence beginning "The aromatic hydrocarbons have . . .", on page 47, should begin, "The alkyl derivatives of benzene have . . .", to make the paragraph intelligible.

It is interesting to note in Chapter 6 that the threshold limits for benzene and toluene in U.S.S.R. are lower than the American and British values; one wonders whether the Trades Unions are aware of this difference.

The binding of this soft-covered book is poor; several pages came away from my own copy after the third opening. The quality of the paper is good.

Notwithstanding these criticisms, the monograph provides a useful compilation of hitherto somewhat scattered information and it should find a place on the bookshelves of all those whose work, whether routinely or infrequently, brings them into contact with toxicology. HAROLD V. STREET

ORGANOPHOSPHORUS ANTICHOLINESTERASES

Organophosphorus Poisons :

Anticholinesterases and Related Compounds. By D. F. Heath. (International Series of Monographs on Pure and Applied Biology. Division: Modern Trends in Physiological Sciences, Vol. 13.) Pp. vii + 403. (London and New York: Pergamon Press, 1961.) 80*s*. net.

THIS book deals with the chemistry, biochemistry and pharmacology of the organophosphorus anticholinesterases and is intended primarily for the research worker in this field. The idea is sound, for probably nowhere else is so much related information collected conveniently together into one volume. Although the book demonstrates the author's considerable experience in all three disciplines, no one person can be expected to possess all the detailed knowledge necessary to write such a book. This is borne out in the section on pharmacology in mammals where numerous errors or distortions of the accepted facts occur. Two examples suffice. Thus on p. 260 the general statement is made that complete tetanic fusion in skeletal muscles occurs at a stimulation frequency of about 25/sec., when 100/sec. would probably be nearer the correct average for mammalian muscles. On p. 267, the author attributes to Zaimis the conclusion that decamethonium blocks neuromuscular transmission by potentiating the action of acetylcholine. From her vast experience in this field, Prof. Zaimis has always been convinced that decamethonium acts by virtue of its own powerful depolarizing action.

For a single author to complete an up-to-date review of this length on such a complex subject he must of necessity prepare his manuscript in a hurry, and some parts of the book, particularly the references, strongly convey this impression to the reader. Fortunately, most of the errors in the references appear to consist only of misspelling of the author's names. However, one reference to work by Blaber and Creasey (p. 186) contains four errors: in the initials of one of the authors, in the year of publication, in the page number of the article and in the species of animal used.

The author is a well-known research worker in the fields of chemistry and biochemistry and the sections of the book concerning these aspects of the subject are written with authority; they contain a wealth of information and should be extremely useful to those starting research in this field. However, the section on pharmacology in mammals is not to be recommended, especially for those inexperienced in pharmacology. W. C. BOWMAN

OPTICAL DESIGN IN INSTRUMENTS

Instrumental Optics

By G. A. Boutry. Translated by R. Auerbach. Pp. xvi+544. (London: Hilger and Watts, Ltd., 1961.) 168*s*.

THE first thing that should be said about this rather expensive book is that the quality of production is outstandingly good. A great deal of attention has clearly been paid to the choice of type, to the setting out of the tables and the mathematics, and to the clarity of the diagrams, in which the essential information is boldly portrayed while the non-essentials are ruthlessly omitted. All this, combined with the quality of the paper and the striking red and black cover, makes it a book which from the æsthetic point of view alone is a delight to possess.

The next thing that needs to be said is that the title gives a rather misleading impression of the contents. There is considerably more straight lens theory in its 22 chapters than might be expected in a book on instrumental optics. The scope of the book can best be judged from the titles of the five sections into which it is divided, dealing with: principles; optical systems with symmetry of revolution; systems with symmetry about a plane; vision and image formation in optical instruments; and main types of optical instruments. Only in the final section can the author be said really to come to grips with optical instruments, more particularly in the case of microscopes. The elegance of the diagrams is also best exemplified in this section, with a very simple but effective illustration (Fig. 360) showing how the exposure spreads through a photographic emulsion, as especially noteworthy.

It might have been expected that a book on instrumental optics would include chapters on interference and polarization and their use in optical instrumentation. Then, too, the special problems associated with, say, optical surveying instruments or spectrophotometers might have been discussed. But perhaps to ask for more is itself a tribute to what the author and translator have already provided.

Special mention should be made of the section entitled "Systems with Symmetry about a Plane". The chapter here on trains of refracting prisms should be particularly helpful; a second rather unusual chapter in this section discusses the symmetry and displacement of the image produced by various sequences of reflecting surfaces; while the third chapter covers the relatively unfamiliar subject of cylindrical lenses.

The original French text was written during the War years 1940–44, so that optical developments which have taken place during the past twenty years are not discussed. At certain points, therefore, there is a slightly dated outlook, as for example, in the reference on p. 320 to the techniques being developed for producing anti-reflexion coatings. This situation has been met by footnote references given by the translator to more up-to-date publications. Other examples are the Stiles–Crawford effect and eye movements which would be given greater prominence in a modern discussion of perception through visual instruments.

The task of translation must have been a mammoth one and it has been carried through with devotion and dedication by Mr. Auerbach. The opportunity has also been taken to correct certain errors in the original French edition. It is perhaps a little disappointing that the opportunity was not also taken to add a bibliography, an omission from the French text which could no doubt be attributed, in part at least, to the conditions prevailing when the book was first written.

W. D. WRIGHT

ROGER JOSEPH BOSCOVICH

Roger Joseph Boscovich, S.J., F.R.S., 1711–1787

Studies of his Life and Work on the 250th Anniversary of his Birth. Edited by Lancelot Law Whyte. Pp. 230+4 plates. (London: George Allen and Unwin, Ltd., 1961.) 32*s*. net.

IT is doubtful whether the reputation of any other natural philosopher of the first rank has suffered such an undeserved eclipse as that of Roger Joseph Boscovich, S.J. Nor is the word 'eclipse' an idle metaphor; for less than fifty years ago this luminary shone with a light undiminished by the passage of a century. As late as 1905 J. J. Thomson drew inspiration from the 'Boscovichian curve'; two years earlier Kelvin had described his own position as 'Boscovichian'; Maxwell gave a critical exposition of his theory in the article "Atom" in the *Encyclopaedia Britannica*, and in his *Dynamical Theory of Gases* based his argument on a mutual 'repulsion' of mass-points (his attribution of actual mass to Boscovich's 'puncta' was in fact an error); Faraday regarded Boscovich's point-centres of force as the only plausible form of 'atomicity', from which he turned away only as his own conception of the field came to dominate his thought; John Robison gave a long and careful exposition of Boscovich's theory from the chair of natural philosophy in Edinburgh in the closing years of the eighteenth century; and, finally, so struck was Priestley by the importance of Boscovich's ideas that he wrote to him with the view of having the *Philosophiae naturalis theoria redacta ad unicam legem virium in natura existentium* (Vienna 1758; revised, Venice 1763) translated.

Despite this cloud of witnesses, and the existence since 1922 of J. M. Child's fine translation of the *Theoria*, it is not uncommon to meet scientists who have not even heard of Boscovich. Fellows of the Royal Society were reminded of the exploits of their former colleague by Mr. L. L. Whyte's article in *Notes and Records* (13, 38); the book of studies now extends this opportunity to the general public: and there is scarcely any member of that public, now increasingly avid for reconstructions of the past, who would not derive pleasure and profit from its perusal.

Most of the articles make no very great claims on the technical equipment of the reader: the admirable "Biographical Essay" by Prof. Elizabeth Hill may be read with enjoyment and profit at almost any level of historical sophistication; for it deals with a fascinating and critical period of European history into the diplomatic, dynastic and ecclesiastical *coulisses* of which the young Jugoslav Jesuit was drawn by his urbane manner (at least in his early years), sympathetic understanding of human relations, elegant Latinity, and capacity for sustained hard work; while his technical realism brought him into consultation about the Pontine Marshes, the dome of St. Peter's, canals, cartography, geodesy, and the equipment of the Brera Observatory near Milan. He became *persona grata* in many quarters—not least in his own native country, the Republic of Dubrovnik, which he cleared of an alleged breach of neutrality towards the British Crown. His intuition of the contingent dominance of Euclidean geometry is only one example of his astonishing insights.

Since the book includes eight further articles on different aspects of Boscovich's scientific work, space does not permit of even listing them; I am able to give them no higher praise than to record that many evenings spent in reading them were followed by days of commerce with many of the original authors referred to. There are an admirable bibliography of Boscovich's works and of numerous relevant secondary sources; also a helpful index of proper names, and of topics dealt with by Boscovich.

Publishers, printers, editor, and Sir Harold Hartley (for his engaging foreword and the part he has played in re-awakening interest in Boscovich) all deserve thanks for a very attractive volume. A few errors—typographical and orthographical—were noted: in the transcription (p. 115) of extracts from Child's translation of the *Theoria* the reference to Newton should be in square brackets, 'found' should read 'bound', and in the next paragraph 'terms' should be 'powers' (*potentias* in the original).

William P. D. Wightman

OEUVRES COMPLÈTES—AND NOTES FOR POSTERITY

Oeuvres Scientifiques Complètes

Par Frédéric Joliot-Curie et Irène Joliot-Curie. Pp. viii+916+10 planches. (Paris: Presses Universitaires de France, 1961.) 100 N.F.

TWO years after the death of Pierre Curie in 1906, his collected works were published by la Société de Physique. In 1924, Marie Curie added a biographical sketch of her husband as preface when this collection was reprinted. Thirty years later, and twenty after her own death, Marie Curie's scientific publications, collected by her daughter, were published as an act of homage by Polska Akademia Nauk in Warsaw. Irène Joliot Curie, in her preface to that volume, wrote: "For the most part these publications no longer have more than an historical interest, such has been the rapidity with which our knowledge of radioactivity has [recently] advanced".

Irène Curie died in 1956, and Frédéric Joliot in 1958; now, in the volume under review, we have the *Oeuvres Scientifiques Complètes* of this second generation of Nobel prize-winners. The preface is signed jointly by their children. Again, in a sense, what is collected is of no more than historical interest—for the rapidity of advance of knowledge has not slackened in the past decade—but the collection is different from its forerunners in one respect which must be mentioned, and its interest is greater in consequence. The novelty is that the present volume contains material that has not previously been published. Let us look first, however, at its main content, at the papers which appeared in the scientific journals over a period of some thirty-five years, and greatly advanced our knowledge, and then return to the rest.

The whole impact of the published work, as all physicists must surely know, is impressive in the extreme. If we look for the highlights they are there: the joint work which resulted in the discovery of 'artificial' radioactivity, and the work of Frédéric Joliot and his collaborators, both before the fall of France and after the liberation, on fission. Equally substantial is the work of Irène Joliot Curie and Savitch, on the radioelement of 3·5 hr. lifetime, which for eighteen months before the discovery of fission held the secret of that process at so short a distance from their grasp. Earlier, there is the note of January 18, 1932, entitled "The emission of protons of high velocity from hydrogenous materials irradiated with very penetrating γ-rays". That, too, was epoch-making. Indeed, the whole corpus is monumental: here is recorded the work of two experimenters of genius.

The unpublished material consists in part of extracts from the *Notices de Titres et travaux* which Irène and Frédéric Joliot Curie wrote in retrospect concerning their published work. Precise dates are not given, but from internal evidence the interval between experiment and gloss must sometimes have been as great as ten years. The result is not uniformly satisfactory, though respect must naturally be accorded to an investigator's personal views of origins and significance when his own work is in question. In the preface to the Warsaw volume, Irène Curie wrote of her mother's early papers, composed in her native language, "That is why it has seemed preferable to publish them without translation—so as to preserve their character as [original] documents". If a similar restraint had motivated the editors of the present volume, the testimony of the original documents here collected would not, in places, have been obscured by the gloss. In his account of the discovery of the neutron (pp. 351–3), Frédéric Joliot comments: "We started to repeat the experiments [of Bothe and Becker]. . . . We learned later that Webster . . . at Cambridge was carrying out experiments by the Wilson method (however without success). . . . This effect escaped Webster's observation . . . which explains why Chadwick did not take up his crucial experiments until we had published our account of the projection of nuclei [by the penetrating radiation]". It is only honest to record the fact that the original documents in the present collection provide convincing evidence in themselves of the inadequacy of the first statement (concerning Webster's experiments) and of the ingenuousness of the plural usage 'nuclei' in the last sentence of this quotation. It is unfortunate that any such rebuttal of witness should be necessary—as it is necessary—in the present context.

The unpublished material is of further interest to the historian in that it includes the full text of the five applications for patent in relation to nuclear reactors and nuclear explosives which Joliot and his collaborators made in May 1939 and April and May 1940. Over the space of a generation the attitude of scientists towards the exploitation of their discoveries had sharpened. In the preface to the Warsaw volume Irène Curie had written, "Pierre and Marie Curie had had no desire to take any patent on the method of extraction of radium. Industry had taken over the process which they had developed almost without modification. . . ." So we have the draft patents of 1939 and 1940—but not the judgment of the law on their validity.

PROGRESS IN SOLID MECHANICS

Progress in Solid Mechanics

Vol. 1. Edited by Prof. I. N. Sneddon and Prof. R. Hill. (Series in Physics.) Pp. xii+448. (Amsterdam: North-Holland Publishing Company; New York: Interscience Publishers, Inc., 1960.) 100*s*.
Vol 2. Pp. xi+331. (Amsterdam: North-Holland Publishing Company, 1961.) 70*s*.

THE problem of acquainting engineers with the essential features of recent research by mathematicians, as well as that by workers in pure science generally, in fields relevant to engineering science and practice, is ever present. This in itself is sufficient justification for these volumes edited by Profs. Sneddon and Hill, which contain review articles of high standard addressed to engineers as well as to mathematicians and physicists.

Volume 1 contains eight chapters. The first, by S. C. Hunter, reviews progress in studies of waves in viscoelastic materials, such as synthetic plastics, and includes accounts of theoretical and experimental investigations. Then K. Marguerre provides an introduction to recent papers on the use of matrices of transmission in problems of vibrating beam systems. The method is described fully for the example of a vibrating beam, and references to the treatment of more complex problems such as vibrating frameworks are given. The present state of knowledge of the mechanics of dynamic expansion of cavities in solids, with particular reference to ductile metals, is surveyed by H. G. Hopkins in Chapter 3. This field involves elastic and plastic behaviour and embraces phenomena due to explosions within solids such as soils, as well as metals. In the fourth chapter, W. T. Koiter reviews general theorems for elastic-plastic solids including uniqueness theorems, minimum principles, plastic collapse theorems and limit analysis and shakedown theorems. Part of this chapter is relevant to the study of the ultimate load-carrying capacity of structures made of ductile metal, but the method of presentation is not well suited to the needs of engineers. Work on dispersion relations for elastic waves in bars is reviewed by W. A. Green in Chapter 5, then in Chapter 6 P. Chadwick surveys thermoelasticity with particular reference to the dynamical theory. This recognizes the interaction of the thermal state and deformation of an elastic solid in time-dependent problems. The seventh chapter, by B. A. Bilby, provides a review of analytical studies of continuous distributions of dislocations relating to the explanation of plastic behaviour of crystalline material. Finally, the treatment of asymmetric problems of the theory of elasticity for a semi-infinite solid and a thick plate in Chapter 8 by R. Muki deals mainly with his own recent work on such problems.

Volume 2 begins with a review by J. E. Adkins of the development of the theory of large elastic deformations with particular reference to the rapid progress made in recent years due to the stimulus provided by the use made of vulcanized rubber. This is followed in Chapter 2 by a survey by M. J. P. Musgrave of recent progress in the theory of propagation of elastic waves in anisotropic media which has applications in seismology and ultrasonic techniques of studying materials and their defects. Then there is a review by J. D. Eshelby of work on effects of elastic inclusions and inhomogeneities in materials, with particular reference to the special problem in which the inclusion or inhomogeneity has the form of a general ellipsoid. The effects are concerned with the elastic behaviour and stress distribution. Mathematical theory of plastic waves, being concerned with the propagation of stresses which are sufficiently large to cause inelastic behaviour of ductile metals, is reviewed by J. W. Craggs in Chapter 4. It is noted that the theory is far from complete at present. Chapter 5, by K. W. Hillier, is unique among the contents of these volumes, since it is concerned entirely with experimental work. Resonance, wave-propagation and direct stress-strain methods of studying the dynamic elastic properties of materials are reviewed. Under the heading "Discontinuity Relations in Mechanics of Solids", R. Hill provides a detailed treatment, with historical background, of the basic analysis for dealing with discontinuity in the dependent variables and their derivatives, in boundary-value problems of continuum mechanics. The final chapter, by M. R. Horne, surveys the field of stability studies of elastic–plastic structures. This chapter is valuable to structural engineers, for the problem of the stability of frameworks in metal which are capable of elastic followed by plastic behaviour is fundamental to the study of the ultimate load-carrying capacity of multi-storey building frames made of steel. It is, moreover, the subject of much present-day research.

The suggestions for future research contained in these volumes are valuable, though more than a year has elapsed since any of the contributions was written. However, the numerous references to original work provide a useful guide to probable sources of present-day research. The editors say in the preface (Volume 1) that the main emphasis in these volumes will be on mathematical techniques of continuum mechanics but that they hope to include surveys of recent experimental investigations in future volumes. This aim has been followed in Volume 2, from which it seems that some aspects of research in theory of structures are also within the scope of the series, to judge by Horne's contribution. Chapters reviewing research into behaviour of frameworks due to dynamic loading and behaviour of shell structures might, then, be appropriate in future volumes.

T. M. CHARLTON

ADSORPTION AND CATALYSIS

Advances in Catalysis and Related Subjects

Vol. 11. Pp. x+384. 12.50 dollars. Vol. 12. Pp. x+324. 11 dollars. Edited by D. D. Eley, P. W. Selwood and Paul B. Weisz. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1959 and 1960.)

VOLUME 11 opens with an article by G. Natta and I. Pasquon in which the authors show in detail how kinetic analysis of propylene polymerization by the triethylaluminium/$TiCl_3$ catalyst system helped to establish the now familiar process of stepwise insertion at a metal–carbon bond. R. V. Culver and F. C. Tompkins give a timely review of surface potentials and the adsorption process on metals. The experimental side of the subject is very properly emphasized and there are some useful tables of the more reliable data. Gas reactions of carbon are described by P. L. Walker, jun., F. Rusinko, jun., and L. G. Austin (87 pages). This is a good, critical account of the subject, and there is an important discussion of the part played by mass transport.

C. Kemball has written a clear and concise chapter on catalytic exchange of hydrocarbons with deuterium. The principles of exchange reactions are followed by examples studied from the point of view of hydrocarbon structure. J. J. Chessick and A. C. Zettlemoyer treat immersional heats and the nature of solid surfaces in a chapter which is a welcome *apologia* for a method that could certainly be more widely used. The last article, on catalytic activation of hydrogen in homogeneous, heterogeneous and biological systems, is by J. Halpern. By collating advances over a broad field and emphasizing the success of electronic interpretations in homogeneous catalysis, the author has written a stimulating chapter.

In Volume 12, T. B. Grimley begins with a short account of the wave mechanical approach to chemisorption. The move away from metals towards semi-conductors as being the most amenable solid type for theoretical study is evident here, and this is strongly accentuated in a later chapter by Th. Wolkenstein (F. F. Volkenstein) on his elegant electronic theory of catalysis on semi-conductors. This is particularly welcome as being the first account of Wolkenstein's work to appear in English. The longest chapter (80 pages) is by D. E. O'Reilly, entitled "Magnetic Resonance Techniques in Catalytic Research". The theoretical background to nuclear magnetic resonance and electron paramagnetic resonance is presented in rather excessive detail, but about a dozen examples of the applications of these methods in various fields of catalytic interest are discussed. In sharp contrast is an article by R. A. van Nordstrand, who presents his extensive experimental data on the X-ray K-absorption edges of the 3*d* metals and their dependence on chemical environment. The correlations here, although purely empirical, are very clearly set out. The link between homogeneous and heterogeneous systems is evident in an authoritative chapter on base-catalysed reactions of hydrocarbons by H. Pines and L. A. Schapp. The authors develop a consistent mechanistic interpretation of these reactions on the basis of carbanion intermediates. The final chapter is a comprehensive review by D. J. C. Yates of dimensional changes in porous solids (notably porous glass) during physical adsorption, together with the related infra-red work on changes in the OH absorption bands. It is always salutary to be reminded that the solid is not an inert partner in adsorption.

These two volumes deserve to be widely read by all those interested in the fundamental aspects of adsorption and catalysis, and the editors are to be congratulated on maintaining such a high level of authorship.

F. S. STONE

DETERGENCY

Surface Activity and Detergency

Edited by K. Durham. Pp. xiii+250+14 plates. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1961.) 35*s*. net.

THIS book is based on a series of lectures given at the Liverpool College of Technology during the winter of 1957–58 by K. Durham, H. E. Garrett, T. G. Jones, A. S. C. Lawrence and D. G. Stevenson.

The first two chapters deal with the properties of detergent solutions with particular reference to surface activity and micelle formation. Some attention is given to the increasingly important non-ionics. The three chapters that follow are concerned with applying these ideas to the basic processes of detergent action—wetting, dirt removal and the prevention of redeposition of the dirt. The separate consideration of these processes is logical since detergency is so complex that no complete theory seems possible. A clear account is given of wetting phenomena and their relation to the washing process, with emphasis on the difficulty of applying simple theoretical models to the wetting of a fabric. Removal of dirt is considered in terms of the modern theories of colloid stability (Derjaguin, Vervey and Overbeek) assuming that 'deflocculation' occurs in the disruption of the dirt-fabric complex. A useful theory of builder action is presented. The importance for efficient washing of maintaining the dirt in suspension is emphasized and the fundamentals of stability are discussed. Then follows an account of ancillary effects in detergent action, including some particularly good photographs of dirt removal from fibres and the cleaning action of foam. Lawrence has written an interesting chapter describing mainly his own work at Sheffield and has presented a plausible picture of the mechanism of detergency of most greasy and oily dirt. The remainder of the book deals with kinetic effects, a subject not discussed in other books in this field, and a brief summary of the evaluation of detergent efficiency.

It is clear from reading this book that there is much more work to be done before a general theory of detergent action can be constructed.

The book successfully combines a reasonable amount of theory with as much practical information as possible—a comprehensive account of the whole field of detergency is not intended. Unfortunately, work published since the lectures has not been included.

In general the book is well written but contains a number of misprints, and more care could have been taken over the lettering on the diagrams. However, these are minor faults and the book is a useful addition to the literature on colloid and surface chemistry. It is highly recommended to technologists working in this field.

G. D. PARFITT

UP TO DATE ON LIGNIN

The Chemistry of Lignin

Supplement Volume, Covering the Literature for the Years 1949–1958. By Friedrich Emil Brauns and Dorothy Alexandra Brauns. Pp. x+804. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1960.) 18 dollars.

INCLUDED in this critical literature review are a few papers, mostly from the U.S.S.R. and Japan, which were not available for inclusion in the original standard work by Brauns published in 1952. *The Chemistry of Lignin*, which is produced in a similar type and style, is of the same length as its predecessor, testifying to the widespread interest, except apparently in Britain, in lignin chemistry and the large amount of work in this field over the past ten years. There is little repetition of the information in the original book and frequent references are made to its contents, although unnecessary disruptions due to this are avoided.

This is an essential reference work for all interested in the chemistry of cellulosic raw materials, for those with little knowledge of the subject it presents in a most digestible form the results of a specialist lignin chemist's struggle to keep abreast with the literature and reconcile the many contradictory claims.

The original literature has been consulted in the majority of cases. As this includes a great number of Japanese papers the author was particularly favoured by the opportunities provided by a Fulbright lectureship at the University of Osaka. This enabled him to obtain assistance from the staff with the translation and with criticism of many of the chapters.

The principal authorities throughout the world have co-operated in providing reprints and overall résumés of their work. Merewether is the only author of a complete chapter, which is that on "The Linkage of Lignin in the Plant", of which he has made a special study.

Excellent author and subject indexes are provided and the twenty-seven chapters are selected and sub-divided in a most convenient logical form, similar to that in the original book, to permit a rapid selection of relevant information. In the preface the author expresses his realization that such a work can neither be complete nor infallible; certainly on first reading no omissions could be found and every effort has undoubtedly been made to make it as comprehensive and accurate as possible.

Brauns and his wife have produced a most pleasing work, and it was a joy to read in such comprehensive detail about one of the remaining major mysteries, as little progress has been made towards the elucidation of the lignin structure in the past decade. It is a pity that so little interest is taken in the United Kingdom in what, after all, is the second most abundant naturally recurring material on this planet. It is to be hoped that this work will provoke more scientists into entering this field, particularly as there is an increasing possibility of workable sources of raw material becoming available in Great Britain, based on the extensive pulping feasibility studies now in progress in Government and industrial laboratories.

J. LUCKINS

PHYSICS FOR THE NON-PHYSICIST

Physics for the Inquiring Mind

The Methods, Nature and Philosophy of Physical Science. By Prof. Eric M. Rogers. Pp. x + 778. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1960.) 48*s*. net.

AT first sight it might seem paradoxical to suggest a course of physics for the non-physicist, but the use of this book will indicate what a wealth of common sense and intelligent understanding lies at the back of the conception of such a course of study. The book is definitely written for the non-scientist, in the hope that he will be brought to appreciate the value of physics as part of a liberal education, and to understand the subject so that he can enjoy the contacts with science and scientists which are part of our modern civilization.

This is surely a very commendable objective, since scientific thought and method are so much a part of our daily lives. I myself think that the book could also be used by bona fide students of physics, since if they pursue the course here prescribed they will certainly get a greater fundamental knowledge of the subject than many of them get by following the more usual courses.

The book is so different from the usual text-book, and it is the author's intention that it should be so. He deals intensively with a series of topics—not so many that learning becomes superficial and hurried, and not so few that he misses the connected nature of scientific work and thinking—to form a co-ordinated structure of knowledge. He does not merely describe experiments and give facts; he aims rather to encourage and stress the value of critical reading, good and sound reasoning and clear thinking, qualities, one would think, sorely needed in our world to-day by men and women whether they are scientists or not.

The mathematics used in the book involves only the simpler parts of algebra and geometry, but a special feature is the unusual type of problem found in copious numbers at the end of each chapter and which are designed to get the student to discuss and reason.

In this particular book the subjects covered are matter, motion and force, astronomy, molecules and energy, relativity, electricity and magnetism and atomic and nuclear physics, but, as the author points out, any other selection of subjects could be made and treated in a similar way.

If one is expected to make one word of criticism it is perhaps that certain parts suffer from over-simplification, but this remark must not be taken too seriously, for the course has been brilliantly conceived and worked out by the author, who deserves congratulations and every encouragement.

I am pleased to have had the opportunity of inspecting this book and of mentioning a few of its many virtues.

T. M. YARWOOD

A CONCISE COURSE OF PHYSICS

A Textbook of Physics

By Dr. R. C. Brown. Pp. xxi + 1424 + xxxvi. (London: Longmans Green and Co., Ltd., 1961.) 60*s*.

THIS voluminous work of more than 1,400 pages incorporates all the material published in separate volumes in the author's *Mechanics and the Properties of Matter*, *Heat*, *Light*, *Sound and Electricity and Magnetism* and is, of course, eminently suitable for all students preparing for the Advanced Level of the General Certificate of Education.

Throughout the book Dr. Brown has made use of his experience as an examiner to take special care in presenting certain topics which he has found to be only partially understood by students. This is a good thing, for there is no doubt that quite a number of candidates enter for the examination with an inadequate knowledge of fundamentals, and these are strongly emphasized in this book.

An appreciable amount of the book deals with work suitable for the Ordinary Level of the General Certificate of Education, and one wonders whether it might not have been better to have had two smaller volumes, one for each level. This is in no sense any criticism of the contents of the book, for Dr. Brown develops his advanced work from the elementary principles quite successfully and thoroughly.

While recognizing the value of M.K.S. units in applied electrical theory and engineering where they are used extensively, the author does not appear to advocate their use in the rather different intellectual climate of advanced physics, though he has an open mind about the use of any particular system of units. He suggests that students who have passed their General Certificate of Education examinations and have to use M.K.S. units afterwards will understand their work better after the firm foundation given by the present syllabuses. This would certainly be true of the good physics student who would have no difficulty with the transition, but the weaker brethren might not find it quite so easy. In connexion with this it is perhaps relevant to point out that at least one of the British universities sets alternative questions based on M.K.S. units in the magnetism and electricity paper, while, of course, the system is widely used in the United States.

Reference is also made in the book to the discussion going on concerning the introduction of more modern topics into the advanced syllabus, and Dr. Brown, very wisely in my own opinion, warns against the inclusion of any such topics if they are allowed to crowd out the more basic parts of the subject. He agrees that all students should know something about modern developments in pure and applied physics, and this belief would be shared by most people; any change, however, would have to be thought out carefully. To stimulate interest among students in the newer work and to serve as an introduction to further reading, two chapters at the end of the book deal with electronics, radioactivity and atomic structures.

This is an excellent and well-written work, and, as one would expect from such an experienced author, a book from which a student should derive great help. T. M. YARWOOD

METALLURGY OF 55 UNCOMMON METALS

Rare Metals Handbook

Edited by Clifford A. Hampel. Second edition. Pp. xvi+715. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1961.) 160*s*.

THE first edition of this hand-book set out existing reference data on thirty-four elements which at that time (1954) were not available in large quantities or were too expensive to warrant wide usage. In the intervening years, many of those originally referred to as 'rare' have become more plentiful in supply and more widely used in industry and laboratory. In this second edition (1961) additions have been made, (chiefly from the rare earth group) and chapters formerly devoted to two metals have warranted separate treatment.

Inevitably, the only method of compilation in a volume of this type is to use specialists in each field and an editor of broad outlook. The result more than justifies the new edition, and this book will be invaluable to all metallurgical libraries, whether concerned with manufacturing processes, development, or research.

In addition to thirty-three separate chapters on individual metals or groups from the periodic system, there is a general review in Chapter 1 on occurrence and processing problems, and a final chapter summarizing physical properties in a form easy to consult, with metals not covered in the hand-book included for reference. Many tables in this chapter show an order of merit in addition to the usual alphabetical list, a fashion which might be more widely adopted in similar reference books.

Each chapter on separate metals gives a full treatment on occurrence, preparation, refining where applicable, properties and applications, with many references for further exploration. Information on such metals as beryllium, germanium and silicon is still obviously affected by commercial security, but extensive publications in recent years on uranium, plutonium and titanium are more fully covered. I was somewhat amused to find niobium described under columbium, and a quarter page of text devoted to an explanation of why the American name has been adopted. The inclusion of metals of the rare earth group is most welcome. During the past few years work in this field has been mainly concentrated in the United States and U.S.S.R. and there is no doubt that interest in these metals is bound to increase with improved methods of separation, refining and fabrication.

This book utilizes the two-column format, which suits a reference book, and the text, diagrams and photographs are excellently reproduced. In spite of the price, this is a work of reference which inevitably will find its way into every laboratory dealing with materials science. C. R. TOTTLE

ANALYTIC FUNCTIONS

Analytic Functions

By R. Nevanlinna, H. Behnke and H. Grauert, L. V. Ahlfors, D. C. Spencer, L. Bers, K. Kodaira, M. Heins, J. A. Jenkins. (Princeton Mathematical Series, No. 24.) Pp. vii+197. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1960.) 40*s*. net.

THIS book contains the principal addresses delivered at the conference on "Analytic Functions" held during September 1957, at Princeton, New Jersey. The authors are all very distinguished, and their articles, which are concerned with the most recent advances in the fields covered, are of a very high standard indeed. In a review of this kind it is impossible to give more than the following brief outlines of the contents.

R. Nevanlinna gives a short account of an absolute calculus. He then proceeds to prove the theorem of Liouville concerned with conformal transformations in Euclidean space of dimension greater than 2.

H. Behnke and H. Grauert contribute a survey article which will be of immense value to those interested in complex analysis of several variables, especially as it contains an extensive bibliography. It deals with attempts to arrive at a suitable analogue of Riemann surfaces. There is considerable dependence on topology of a high degree of sophistication.

Teichmüller showed that the space of Riemann surfaces with generators of genus g greater than unity has a natural metric by which it is topologized as a $6g - 6$ dimensional manifold. L. V. Ahlfors in his article shows that over this topology is a unique complex analytic structure with respect to which the elements of the Riemann matrix are analytic functions.

D. C. Spencer applies a technique that he and Kodaira used earlier to describe the deformation of complex analytic structures to other structures. Particular attention is directed to real foliate structures and to structures defined by pseudogroups in the sense of E. Cartan.

After an introduction to quasi-conformal mapping and Fuchsian groups L. Bers proves a theorem due to Teichmüller. This result, which leads to the natural metric considered in Ahlfors's address, is that between any two Riemann surfaces of genus g greater than unity there is an essentially unique quasi-conformal mapping of constant dilatation.

K. Kodaira deals with structures of complex analytic surfaces, that is, complex analytic manifolds of dimension 2.

M. Heins surveys results concerned with a certain aspect of conformal mapping of Riemann surfaces. The author has made many contributions to the subject, which is still in an early stage of development.

J. A. Jenkins introduces an idea due to Teichmüller that certain kinds of extremal problems in geometric function theory are associated with quadratic differentials. The author then states his 'general coefficient theorem'. Best possible inequalities are found for the first few coefficients of univalent functions, including the known bounds for the third coefficients in the regular and meromorphic cases.

J. CLUNIE

MODERN ECONOMICS

Economics

The Science of Prices and Incomes. By H. Speight. Pp. 671. (London: Methuen and Co., Ltd., 1960.) 42*s*. net.

IT is difficult to do justice to Mr. Speight's book in a short review: it is a very long book (670 closely packed pages), it contains much that is excellent, it gives ample proof of the author's wide knowledge of, and enthusiasm for, his subject, and yet I am uncertain to what extent the book meets the requirements of university students and students reading for qualifying examinations of professional associations for whom the book is intended.

Mr. Speight writes (p. 290) ". . . the function of a text-book is to present its subject as it exists to-day . . ." and this he has done. The result is a most modern text-book. But this modernity has exacted a price; a long book and, in spite of the length, the omission of some basic material (for example, formal analysis of selling outlays, indifference curves and the demand for complementary goods), and a brevity of exposition of basic theory which, though in the main sound, is sometimes incomplete (for example, references are made to the convexity of a consumer's indifference curves but no formal analysis is made of the convexity) and occasionally ambiguous or wrong (such as the discussion using Figs. 52 and 53, p. 207, which is wrong about the response of the intramarginal firms to an increase in market price). Little that has concerned economists in the post-war period has escaped Mr. Speight's net, from the theory of games to the Radcliffe Report on the working of the monetary system. Mr. Speight tells us that "one of the most difficult tasks in the actual writing of the book was deciding where to stop". There is plenty of scope for controversy on what should be included in a basic text-book, but my preference is for a number of short but thorough books which go out of their way to meet the difficulties of students. Perhaps it is time we decided that the "subject as it exists to-day" is too big to be dealt within a single volume.

The book covers almost the whole range of economics. Part 1 deals with the nature of economics, wealth and income. Part 2 deals with the theories of demand and production. Parts 3 and 4 deal with welfare economics and the economics of money and banking. Part 5 deals with the theory of income and employment, the trade cycle, public finance and fiscal policy, international trade and finance, and concludes with a chapter on stability and growth. The latest analytical devices are used throughout. It must also be mentioned that the book contains a lot of interesting factual material on economic structure and institutions, and some which is relevant to the assessment of the validity of the theory being discussed (such as the influence of the rate of interest on investment decisions).

The later chapters are not claimed to be more than introductions to the major themes of their subjects, and if they stimulate the reader to further reading they will have done their job. This is equally true of many of the earlier chapters such as those on the theory of the firm and those sections dealing with welfare economics. Supplementary reading is automatic in the universities and is laid on to supplement lectures and as a basis for written work. Much of Mr. Speight's material will be valuable in this connexion as a first approach, for example, the various sections of his book dealing with the rate of interest. The private student, however, will not find a number of parts of this book easy going and is likely to wish that the author had spent more time on their potential difficulties at the expense of some of his marginal material.

The book is well produced, attractive to look at and the contents are very clearly laid out. It is good value for money. A few minor errors, however, need correction. The reference on p. 79 to Fig. 9 should be to Fig. 10*a*. The text on pp. 83 and 84 refers to letters N, Q, D and Y on Fig. 12, but this figure does not contain these letters. The three sections of Fig. 43 on p. 194 should be labelled A, B and C. On p. 498 there is a reference to $K = \frac{1}{2}$; this should read $c = \frac{1}{2}$ or $K = 2$.

H. BURTON

FOSSIL MAMMALS

Traité de Paléontologie

Tome VI, Premier Volume: Mammifères—Origine Reptilienne—Évolution. Publié sous la direction de Jean Piveteau. Pp. viii+1138, 970 figs. + 1 planche. (Paris: Masson et Cie., 1961.) Broché 240 N.F.; Cartonné toile 254 N.F.

WITH the publication of the first volume of Tome VI, only one volume (Tome IV) remains to complete Piveteau's *Traité de Paléontologie*, which began publication in 1952. Of the eight volumes comprising the work, three are devoted to invertebrates, two to the lower vertebrates and three to the mammals, one of the latter being exclusively devoted to Primates—a heavily anthropocentric bias. Nineteen authors contribute to the volume under review, and of these fourteen are French, the major contributions being made by Piveteau, Lehman, Viret and Dechaseaux. The first third of the volume deals with mammal-like reptiles; the second with mammalian anatomy, classification, geographical and stratigraphical distribution and the Mesozoic Mammalia; the final third treats systematically with Carnivora, Cetacea and Artiodactyla—an oddly unnatural grouping of orders.

The *Traité* is one of a series of recent French science treatises, a field which was previously so typically Germanic. Piveteau's treatise is a worthy successor to Zittel's long-outdated *Grundzüge der Paläontologie*. This volume of the *Traité* will be a valuable reference work for zoologists and geologists in general besides mammalian palæontologists in particular. The illustrations are plentiful and clearly reproduced, considering the diverse quality of many of the originals. The table of contents is very inadequate, just over one page in a work of more than 1,100 pages, and lack of systematic tabulations within the text will impair the work's ease of use. A stricter editorial policy would have made for more uniform treatment of subjects and more consistent revisions, for some parts give the impression of having been written a decade ago. The work will be used by many without a detailed knowledge of stratigraphy, yet it lacks a correlative table of stratigraphical terms.

Space does permit comment on each order. The editor is to be congratulated in obtaining the services of Orlov and Tchudinov to describe the Russian therapsid material, all too little known in the West. The therapsids are comprehensively treated, abundantly illustrated and the problems of their relationships, so much *sub judice* at present, are succinctly summarized.

A brief chapter is devoted to geographic and stratigraphic distribution of Tertiary mammals, with maps of each continent and lists of main sites; by a peculiarly Gallic twist of logic, Europe comprises only France, Western Germany and Spain. The palæontologist would have welcomed more maps and fewer illustrations of palæolithic cave art, so well dealt with elsewhere. The inclusion with each section of an account on brain-casts is imaginative and laudable.

In the section on carnivores, practically all genera up to 1945, except those the validity of which is suspect, are mentioned and their characteristics briefly noted. No less than fifty new genera of fossil carnivores have been described since 1945 (excluding Kretzoi's re-naming of known forms) and of these only eleven are mentioned. This omission of several important new faunas described within the past two decades is an unfortunate defect. Other groups are admirably up to date, as, for example, the Artiodactyla, where the treatment of this very large and complex order has been skilfully handled by Viret.

It is unfortunate that so useful a volume should be priced outside the reach of many individuals.

R. J. G. Savage

THE DIVERSITY OF URBAN LIFE

British Towns

A Statistical Study of Their Social and Economic Differences. By C. A. Moser and Wolf Scott. (Centre for Urban Studies: Report No. 2.) Pp. xii + 169. (Edinburgh and London: Oliver and Boyd, Ltd., 1961.) 30*s*. net.

At the 1951 census there were in England and Wales 157 urban areas with a population of not less than 50,000. Diversity was perhaps their most striking characteristic. In size they ranged from Harrogate with 50,000 to the Administrative County of London with 3·3 millions. The proportion of the population over 65 years varied from a mere 5 per cent in Dagenham to 25 per cent in Worthing. Over the two previous decades West Ham had declined in size by 42 per cent while in contrast Huyton had increased by 973 per cent. Annual retail sales per head of population ranged from £38 in Huyton to £244 in Worcester. Using 57 variables and data relating mainly to 1951, Moser and Scott present an empirical study of the rich variety of urban life in these 157 centres of population. The variables embrace demographic characteristics, housing, economic activities, voting behaviour, indices of health, and some aspects of education. Chapters 2 and 3 describe this diversity in some detail. Chapter 4 considers the matrix of 1,596 zero order correlations between the variables taken in pairs. Chapter 5 uses multivariate analysis to extract four principal, orthogonal, components of the form: $\xi_i = \Sigma a_{ij} x_j$, where the x_j are the original variables in standard form, which together absorb 60 per cent of the variance. Chapter 6 considers each town as represented by a point in four-dimensional space with the ξ_i as co-ordinates. All but two of the points thus derived are grouped into an arbitrary number of clusters so that the mean distance of points in a cluster from their centre is less than the distance between clusters. This clustering is interpreted as a 14-point classification of the towns of England and Wales. The Administrative County of London and Huyton-with-Roby in Lancashire defy classification. Chapter 1 is a short summary of the volume, and the book closes with a series of appendixes on the original data and a brief comparison with Scotland.

The authors are scrupulously fair about the limitations of their method. The factors yielded by component analysis will depend on the selection of the original variables. That selection in turn depended in part on the authors' ideas of what was relevant to a description of the varied pattern of urban life, but perhaps more on the availability of comparable data. Some of the diversity will arise simply from the arbitrary nature of the boundaries of our towns. Carve out a slice of the low-status area of north Merseyside, label it 'Bootle', treat it as a separate urban area, and it must be expected that its characteristics will differ markedly from those of Liverpool with its rich mixture of all classes. Let Parliament re-draw the Local Government map and the method may yield quite different components. There is little even to suggest that similar results will follow from the use of data shortly to become available from the 1961 census. But the experiment must certainly be tried. If the same components again emerge then it is time to carry the investigation much further. As the authors themselves remark, this is a pilot study. It is perhaps best regarded as a meticulous set of laboratory notes, awaiting further evidence and, above all, awaiting a unifying theory.

H. Silcock

TERMS OF REFERENCE

The International Dictionary of Applied Mathematics

Editor-in-Chief: Prof. W. F. Freiberger. Pp. viii + 1173. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London, D. Van Nostrand Company, Ltd., 1960.) 187*s*. 6*d*.

In the preface to this considerable compilation, the editors state that the dictionary "defines the terms and describes the methods in the applications of mathematics to thirty-one fields of physical science and engineering". This is a fair claim, but a prospective reader may pertinently inquire for whose benefit the set of definitions is intended. The dust-cover declares that the "range", "scope" and "number" of "the more than 8,000 entries in this volume bring to those of many disciplines—from physicist to chemist, from aeronautical engineer to metallurgist—an invaluable aid for ready use in the laboratory, plant or office wherever mathematical applications are needed to-day".

To this end, the editors have obtained, from some forty distinguished authors and translators, contributions which are models of succinctness and these have been disposed in alphabetical order and cross-referenced. The terms defined range from "Bethe-Salpeter Equation" and "Blunder" to "Yang-Feldman Formalism and the S-Matrix" and "Year". This bespeaks comprehensiveness perhaps, but alas, too often it happens, in face of the requirement for accurate and concise definition, comprehensibility flies out of the window. Moreover, we may not follow her flight since, in general, we have not the radar of references. Nor do the essential multilingual indexes in German, Russian, French and Spanish help us in our difficulty.

Is this dictionary then a dead loss ? (A term, by the way, it has not chosen to define.) Not entirely. But by its present standard of production it must count as a curate's ostrich egg; for besides the disparity of content, the typography shows many signs of inadequate proof correction (for example, SCARE, PYTHAGOREAN What a title for schoolboys' science fiction !)

In according such a qualified reception to a work which must have taken a large number of man-hours, it remains to offer an opinion about the reasons for disappointment. Principally, it would appear that the contributors did not have a common audience or readership in their several minds. This is an editorial shortcoming basically, as to a large extent are the other faults mentioned above.

To obtain the standard expected of a good work of reference, a clearer vision of the likely consultant and his requirements, a considered policy for references and bibliography and greater care in proof correction seem essential.

The present edition may serve a limited purpose in libraries. M. J. P. Musgrave

A LEXICON FOR THE SCIENTIFIC ERA

Webster's Third New International Dictionary of the English Language

Editor in Chief: Dr. Philip Babcock Gove. Unabridged. Pp. 56+2662. (London: G. Bell and Sons, Ltd.; Springfield, Mass.: G. and C. Merriam Co., 1961.) 420*s*.

To quote the statement inside the jacket of this monumental work: "A new full-scale 'Merriam-Webster' dictionary comes but once in a generation". It is now twenty-eight years since the last edition of this dictionary, or a dictionary planned on the 'International Webster', lines appeared. The present dictionary is, in fact, an entirely new one, being called *Webster's Third New International Dictionary* rather than the third edition of *Webster's New International Dictionary*.

While there has been a large number of additions and retractions from the 1934 edition, *Webster's Third New International Dictionary* maintains the traditional Webster style, and, with more than 450,000 entries, many of which are illustrated, can be considered as almost an encyclopædia in miniature. It represents a great development on the second edition and to some extent as a reduction (3,210 pp. to 2,662 pp.). This can be accounted for by the fact that not only has the Bibliographical Section been removed, but also the Gazetteer Section. The main developments and extensions lie in the way in which the editors have capably handled the flood of scientific, engineering and medical terms which have evolved during the past twenty-eight years. This has been admirably done by the permanent scientific editorial staff, supplemented by some eighty outside scientific consultants.

Biologists are well served in that, besides explanations of general terminologies, family, specific and common names of animals and plants are listed and cross-referenced. For example, the description under the entry "Twayblade" is supplemented by reference to "*Listera*" and "*Liparis*" and vice versa: "Beaver" gives reference to "*Castor fiber*" and vice versa, etc. For the chemist, elements and compounds are treated individually, and information is supplied concerning their properties, occurrence and uses, and in the case of elements this is followed by a detailed list of their more general compounds. The compounds entered under "Nitrogen" extend to some two and a half columns of text. Named effects and laws in chemistry, physics and mathematics, including such entries as Bohr's theory, Krebs' cycle, Euler's formula, Stoke's law, etc., are defined and explained. It is pleasing to see such terms as "Maser" defined, not only technically, but also from the etymological point of view, for it would be a great pity to lose track of the fact that such words are really only abbreviations—in this case, "*m*icrowave *a*mplification by *s*timulated *e*mission of *r*adiation".

Mineralogical terms are defined and formulæ given to minerals with brief outlines of their properties; crystallographic forms are defined and usually illustrated. A full-page illustration is presented of man dealing with the muscular system and skeleton, and in general anatomical and physiological terms are well explained, and also pathological terms with an outline of their ætiology.

The edition which appeared in 1934 was priced at 85*s*. and could be considered to stand in good stead even against such works as the great *Oxford English Dictionary*. First, this was due to the disparity of prices, secondly, a utilitarian difference lay in the disparity of sizes. In a review of the second edition (*Nature*, 134, 603; 1934) it was claimed that "Even the smallest study or office could accommodate "Webster" (which might indeed stand permanently on the corner of a desk), the O.E.D. spreads itself luxuriantly over several feet of shelf-room". This is still the case even with *Webster's Third New International Dictionary* at 21 guineas—the production of which necessitated an outlay of more than 3,500,000 dollars (£1.25 million)—however, it would be necessary to have rather a large desk if one wanted to work and maintain Webster (approximately 10 in. × 13 in. × 4 in.) on it.

Webster's International Dictionary was originally designed for the educated practical citizen of the world. It has now gone much further and is indeed a scholarly and technical reference work, a beneficial acquisition to any office or library.

R. J. Fifield

SHORT REVIEWS

A Scientist Who Believes in God

By Dr. H. N. V. Temperley. Pp. 176. (London: Hodder and Stoughton, Ltd., 1961.) 15*s*. net.

THERE is an increasing number of books by men of science concerning their faith and Dr. Temperley's is a welcome addition to the range. In the author's words: "The central problem is whether the whole body of evidence before us justifies the inference that the universe is directed by a Mind, or whether we must conclude that the existence of the human race is the accidental result of certain forces acting in a particular environment. . . . To sum up, the book is intended to be a survey of, and a guide to, the available evidence rather than an attempt to sell any particular brand of philosophy, theology or churchmanship, or any special scientific theory". Dr. Temperley has succeeded in this objective, and his desire to help young people to make up their minds about fundamental religious questions should receive wide recognition. Every thoughtful reader, whether young or old, can benefit by this adequate and frank discussion of religious problems. No doubt the author's wide experience as teacher and research worker in physics and biophysics, both at Cambridge and in the United States, is reflected in his own confession of faith.

Special attention is directed to the case for the 'materialist evolutionary' theory of the universe, followed naturally by that for a 'theistic' interpretation. Specific lines of evidence such as that from within, from Christianity, and from other sects and faiths are pursued with clarity. Of special interest is a modern modification of Paley's well-known teleological argument. The last chapter of the book is devoted to the author's own position and is all the more convincing as his journey back to belief was made from the realm of complete agnosticism.

H. D. ANTHONY

The World of Learning, 1961–62

Twelfth edition. Pp. xiv+1359. (London: Europa Publications, Ltd., 1962.) 140*s*. net.

THE current edition of *The World of Learning* continues the policy of providing the widest possible guide to the world's cultural institutions, showing the addresses, and names of the leading officials, of the world's learned societies, research institutes, libraries and archives, museums and art galleries, universities, colleges and technical institutes. A list of the professors of most universities is also provided, and this year, in response to numerous requests, the telephone numbers of a large number of universities and certain other institutes have been included. It also includes details of Unesco, giving its origin, aims, functions and activities, followed by, in alphabetical treatment, each of the member countries.

The present edition shows an increase of eighty pages from the eleventh edition, necessitated by the rapid development of the newly emerged nations of Africa and Asia and the intensification of scientific and cultural activities in the rest of the world. The contribution from the U.S.S.R. shows a small increase, but still remains at the regrettably low figure of thirty-three pages, compared with the total of two hundred and twenty from the United States

It is to be regretted that *The World of Learning* still does not include a name index. With present-day 'punch-card' sorting techniques, such a compilation should not represent the impossible task that faced the organizers of *Index Generalis* when completing the twenty-first edition in 1955. The index to this massive work included something like 125,000 entries and extended it by some 400 pages. If necessary, the index to *The World of Learning* could be prepared as a supplement.

Persons and Perception

By Leslie Paul. Pp. 231. (London: Faber and Faber, Ltd., 1961.) 25*s*. net.

THIS volume is interesting more for some of its 'asides' than for its main theme. The author considers the reasonableness of metaphysical inquiry, the impasse over perception, the protest against bifurcation, the analysis of feeling, and the status of percepts. All this is not very much more than a book about books, mostly those of the great philosophers. But at the end of Chapter 1 we find—after a reference to the æsthetic satisfaction of mathematical physics—a noteworthy paragraph on the present obsession with scientific specialization Those, in fact, whose outlook is not scientific would be worse humanists if they were to abandon their own type of wisdom. Metaphysics, unfashionable no doubt, needs no apology or backward glances.

With this in mind, we turn to Chapter 4 and read a charming account of how any graceful bodily action is ruined if the performer becomes self-conscious. He simply does not know how it is done; mastery is completely natural. We all know this, but it is tempting to go a stage further (Dr. Leslie Paul does not quite venture thus far). and apply much the same criterion to accomplishments of the mind. Perhaps the greatest achievements in, for example, pure mathematics are entirely unselfconscious. They become something far less when pressed into service for the satisfaction of examiners, or even for an occasional lecture.

Along these lines, the axiology of thought will have to advance, if the author's metaphysical hopes are to reach fruition.

F. I. G. RAWLINS

The Coil of Life

The Story of the Great Discoveries in the Life Sciences. By Ruth Moore. Pp. xv+418+vii+16 plates. (London: Constable and Co., Ltd., 1961.) 40*s*. net.

RUTH MOORE is a science reporter to an American newspaper, and, in this book, combines flair for journalism and considerable scholarship to produce a dramatic account of the great discoveries in biology and allied sciences over the past 200 years. The story begins with Lavoisier, and, besides more familiar figures, describes the work of Bichat, Beadle, Tatum and other investigators who have made important contributions to the unravelling of the properties of life. Developments over the past ten years are explained with rare skill even if the author's imaginative gifts sometimes exceed her concern for objectivity. With its many fine illustrations *The Coil of Life* could be read profitably by many who wish to know more about the science of life. To help them to a sound start with better perspective, the publishers might remove the dust-covers and their extravagant blurb about great discoveries "which have at last virtually solved the riddle of life". T. H. HAWKINS

The Boy's Country Book

Edited by John Moore. Pp. 320. (London: William Collins, Sons and Co., Ltd., 1961.) 12*s.* 6*d.* net.

ONE of the drawbacks of growing up is a gradual abatement of curiosity. The reaction of many people to the pressures of life is a form of withdrawal, a cutting down of interests, sometimes deliberate, sometimes not, leaving eventually a limited number, often entirely spectator interests or indoor ones. City children of parents who reach this stage may never have their eyes opened to the possibilities of out-door country interests unless schoolmasters or others take a hand. This book should help. It should be in public and school libraries.

Mr. Moore has enlisted the help of some twenty authors of national standing. Each has contributed an outline of his (or her) own particular sport, pastime or recreation which could kindle an interest, and has recommended one or more specialist books where its details can be followed up.

Part 1 has five chapters: route planning, lightweight camping, travel by horse, on not getting lost and on outdoor food. In Part 2, nine chapters range from rock-climbing to gliding, through sailing, angling and other interests. Parts 3 and 4 have nineteen chapters which cover a range from geology and archæology to a wide variety of natural history topics.

No money has been spent on expensive half-tone illustrations. Each chapter is headed by a simple drawing, and in a few instances simple illustrations clarify the text, but in general the book gives value for money in useful print rather than eye-catching pictures. H. DUNNICLIFF

Instructions to Young Naturalists

Part 4: Fossils. By Dr. W. E. Swinton. (The Brompton Library.) Pp. 112+13 plates. (London: Museum Press, Ltd., 1961.) 12*s.* 6*d.* net.

THIS is more than a set of instructions to young fossil hunters, it is the story both of conditions on the Earth's surface and of the animals that have roamed that surface during the past five hundred million years.

Magnificently illustrated with line drawings and photographs, it is a most readable and absorbing account. Dr. Swinton takes care to explain the theoretical problems involved in simple, lucid language; and long, resounding names, which so many young palæontologists will enjoy rolling their tongues around, are provided with their meanings or origins—a truly educational touch.

The practical nature of such a hobby is, nevertheless, always to the fore and constant reference is made in the text to sites at which the fossils described may be sought. The chapter of detailed collecting instructions gives further geographical information, along with a map of fossiliferous localities. This is followed by a useful list of reference books and museums from which further information may be gleaned.

Young fossil-hunting enthusiasts are a demanding race, but all should find stimulation as well as instruction in the pages of this book.

It is not, however, a book for the half-hearted. Dr. Swinton seems to sense their easily induced boredom and his style is too apologetic to rouse them from a prejudiced inertia.

The only serious criticism that can be levelled is the virtual rejection of the plant world. Apart from two photographs and a few passing references to the food of animals, these sustainers of life, on the energy transformations of which the whole of evolution has depended, are completely ignored.

Young naturalists who live in coal-mining areas will find this particularly frustrating, while academic botanists may justifiably feel that the title should have had the word 'Animal' inserted.

J. S. FORDHAM

The Young Scientist's Companion

A Book of Information and Advice to all concerned with Science. By Maurice Goldsmith. Pp. 160+4 plates. (London: Souvenir Press, Ltd., 1961.) 15*s.* net.

THE book claims to be "an information guide for all concerned with science" and its weakness is that it attempts too much. For example, the schoolboy is unlikely to wish to present scientific films or to use wall charts, so that lists of addresses relating to them are not helpful to him, while the science teacher or technologist can get fuller information from professional sources. The information given on careers is necessarily limited, but it could have been extended had the reader been referred to *Whitaker's Almanac* for the addresses of professional bodies, which occupy four pages. There are some useful notes on equipping a 'home laboratory' but few suggestions about what to do with the equipment. The notes on science fiction could well be omitted since the schoolboy is well informed and the adult who is an addict will know his way round the public library.

The best features are perhaps the illustration of scientific method as it was applied in developing the periodic table of elements and the commentary, which contains some interesting extracts from the writings of great scientists and of present-day scientific workers as well as elaborations of points mentioned in the text. The book list is also valuable.

The book is one of a series of *Companions* so that the author was presumably expected to fit a little of everything into 150 pages or so. He is not to be blamed if the resulting volume appears superficial.

K. W. LYON

Vanishing Animals

Preserving Nature's Rarities. By Philip Street. Pp. 232+20 plates. (London: Faber and Faber, Ltd., 1961.) 21*s.* net.

THIS book concerns one of the greatest problems facing naturalists and zoologists throughout the world: the conservation of wild life. Particular emphasis is given to rare species and to those threatened with extinction.

It may, therefore, be thought to be a book for the specialist, but this is not so. The book makes a fascinating study for all animal lovers, and is very easy to read. The author writes lucidly from his wide research on the subject, with the result that few will fail to be entertained, and many will gain a deep interest in the welfare of fauna.

The book covers a wide range. Fresh information on the habits and behaviour of various animals is disclosed: for example, the fact that the sea otter spends much of its time floating on its back with its arms resting across its chest or using its chest as a table for its food. Odd corners of the Earth, such as the Galapagos, Islands, are mentioned. Past, present and future problems are considered.

There are twenty black-and-white plates that are actual photographs. These provide rare glimpses for the layman of some animals: for example, fur seals and the Komodo dragon of Komodo Island. Photographs come from such sources as David Attenborough and Mrs. Peter Scott, as well as from scientists and zoologists of many countries.

B. J. G. Maitland

The Birds of the British Isles

By Dr. David Armitage Bannerman. Illustrated by George E. Lodge. Vol. 10: Scolopacidae (conclusion); Charadriidae; Recurvirostridae; Haematopodidae. Pp. x + 320 + 23 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1961.) 63*s*. net.

With the appearance of this tenth of his dozen volumes, Dr. Bannerman approaches completion of his great undertaking. Here he concludes his account of the sandpiper family (mainly those species named in English from the colour of their 'shanks'), deals with the smaller number of the plovers, and ends with chapters on the avocet, the stilt, and the oystercatcher. As in the ninth volume, many of the species are more or less uncommon visitors to the British Isles from distant breeding grounds; it is therefore valuable to have the contributions that Dr. Bannerman has obtained from American, Russian and other ornithologists on aspects of life-history that could not otherwise have been fully covered. There are also British contributions on special topics such as the breeding habits of the dotterel and greenshank in Scotland, the disappearance of the Kentish plover as a British breeding bird (last known to nest in 1956), and the recovery of that status by the avocet under careful protection in East Anglia.

Landsborough Thomson

Living Fishes of the World

By Earl S. Herald. Pp. 304 (300 illustrations). (London: Hamish Hamilton, Ltd., 1961.) 63*s*. net.

Had there been fewer errors in the text, this book could have made a noteworthy addition to the list of popular works on fishes. The colour and monochrome photographs are very good, and some are surely unique. Although much of the text passes muster, there are far too many errors. Some, like the inconsistent spelling of certain specific names and placing Phallostethidae under a heading "Suborder Polynemoidea", may be due to careless proof-reading. Others cannot be so dismissed. There are unsettling contradictions; for example, we are told that the arawara (*Osteoglossum*) and *Scleropages* are both mouth-breeders, and later in the section we are told that the breeding habits of the arawara are unknown, but it is suspected of being a mouth-breeder. The author's views on external gills, their occurrence and homologies are confused. Who would agree that the external gills of *Polypterus* are only comparable with the embryonic gills of larval sharks, and that they are not like the external gills of lung fishes? The section dealing with cichlid breeding habits needs tightening up, and it is a pity that *Tilapia melanopleura* (one of the non-mouth-breeding species) should be used to illustrate "African Mouth-breeders". One final example: in view of the many articles and papers on the cœlacanth it is surprising to read that one of its "anatomical distinctions include . . . a large lung . . ."; it is stretching definitions too far to describe this admittedly large but narrow, fat-filled and solid structure as a lung.

These and other errors could easily be corrected in a revised edition, which I hope will appear, for there is a lot of valuable material in this book which the non-professional zoologist would not easily find without searching widely.

P. H. Greenwood

The Chrysomelidae (Coleopt.) of China and Korea

Part 1. By J. L. Gressitt and S. Kimoto. (Pacific Insects Monograph, No. 1*A*.) Pp. 300. (Honolulu, Hawaii: Entomology Department, Bernice P. Bishop Museum, 1961.) 4 dollars; 29*s*.

As the authors state in their introduction, the Chrysomelidae is one of the largest families of beetles. It probably includes more than 50,000 species in the world. Therefore, any modern work dealing comprehensively with the family as found in a single zoogeographical region of the world is to be welcomed. Unfortunately, it falls between two stools. It is more than a simple catalogue, but much less than a comprehensive hand-book to the fauna of the region. In short, the authors seem to have attempted to do too much in too little time and above all, space. It is a pity that this work was not modelled on that invaluable contribution to our knowledge of the Chrysomelidae, the three volumes by S. Maulik in the *Fauna of India*.

The illustrations in the present work are superb and the descriptions of new species good. The keys to the sub-families, genera and species are clear and a very valuable tool to all workers on the group. The authors are to be congratulated on the monumental effort needed for their compilation. However, it would be useful to have short descriptions and notes on each genus and species. One would then be able to check identifications and to determine new species. It is pleasing to find that the host plants are stated where known; but fuller biological notes on both larvæ and adults would be useful. It is to be hoped that the final volumes of the Chrysomelidae will include a comprehensive and easily used index at the back. The format of the *Insects of Hawaii* is to be recommended for all future volumes.

B. J. Selman

The Yorkshire Jurassic Flora

By Prof. Thomas Maxwell Harris. 1: Thallophyta-Pteridophyta. Pp. ix + 212. 71 text-figs. (London: British Museum (Natural History), 1961.) 80*s*. net.

This is the first of two volumes on the Jurassic flora of Yorkshire. The discoveries of fossil plants made since the early part of the nineteenth century in Yorkshire have probably contributed more to our knowledge of Jurassic plants than those made in any other part of the world. Nathorst, Sir Albert Seward, Dr. Hamshaw Thomas and Prof. Harris have carried out most of the more detailed scientific investigations of this flora. These two volumes by Prof. Harris will replace Seward's *Catalogue* of 1901. He assembles all the important information and has examined, using modern methods, the evidence that the fossils afford. He has also clarified the nomenclature, which was in a chaotic state. He has been able to define specific differences in some critical genera, for example, *Coniopteris*, and gives clear descriptions of species, including many that are new. This first volume is illustrated with numerous line drawings and silhouettes which are for the most part excellent, but there are a few (for example, Fig. 55*B*) which are so simplified that they do not resemble an actual specimen. I should have preferred that use had been made of some photographic illustrations to give an idea of the nature and beauty of some of the fossil material and of the cuticle and transfer preparations that may be prepared from it. Such illustrations would assist in substantiating the statements made and would permit overseas workers who have not handled the material to acquire a greater appreciation of Prof. Harris's methods of investigation.

These volumes will be of great value to palæobotanists and to the curators of the many museums in which there are collections of Jurassic fossil plants.

JOHN WALTON

Advances in Ophthalmology

Vol. 11. Edited by E. B. Streiff. Contributors: G. Ten Doesschate, W. A. Manschot, L. Matiaska, and J. Stepanik. (Bibliotheca Ophthalmologica, Fasc. 58.) Pp. vi+274. (Basel and New York: S. Karger, 1961.) 60 Swiss francs.

THE concept of collagen diseases was introduced about twenty years ago and, in the first paper in this volume, its impact on ophthalmology is examined. Descriptions are given of the essential features of generally accepted collagen diseases and, against this background, the pathological and clinical manifestations of certain disorders of the various tissues of the eye are carefully analysed. The conclusions are presented with an excellent combination of conciseness and clarity.

The second paper deals with the causes of blindness in the neighbourhood of Basle. To those familiar with Sorsby's surveys in England and Wales it will be interesting to find that, in Basle, uveitis is the main disease causing blindness, while primary glaucoma occupies the sixth position, being a less frequent cause of blindness than retinitis pigmentosa.

About half this volume is occupied by a treatise on tonography, dealing thoroughly with the theoretical basis and sources of error of the technique, but far less extensively with its diagnostic value. Adequate accounts are given of ocular rigidity, tonometric calibration, episcleral venous pressure and other factors of fundamental importance in the determination of the facility of aqueous outflow. Nevertheless, one is left with the impression that a somewhat empirical method of evaluating the results achieves the best differentiation of glaucomatous from normal eyes by tonography.

Finally, there is a brief review of the history of ophthalmology which attempts little more than giving a list of the more important references.

J. GLOSTER

Advances in Applied Microbiology

Vol. 3. Edited by Wayne W. Umbreit. Pp. xi+421. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1961.) 93*s*.

TEN widely diverse topics are discussed in the third volume in this series. Three are primarily concerned with technique: preservation of cultures by freeze-drying, by R. J. Heckly; the hazards of accidental infection in the microbiological laboratory by M. A. Chatigny; and the application of chromatography to the determination of organic acids likely to be of interest in studies of microbial metabolism, by A. C. Hulme. Microbial metabolism is considered in articles on the cardiac lactones by E. Titus, on the oxidation of aromatic compounds by M. H. Rogoff, and by J. D. Bu'lock, who contributes a stimulating discussion of the relationships between general and secondary metabolites with particular reference to antibiotic synthesis. Taxonomy is represented by a scheme put forward by E. Baldacci for the classification of the actinomycetes. In the remaining articles F. M. Schabel, jun., and R. F. Pittillo discuss the use of micro-organisms in screening tests in the search for anti-tumour drugs, D. J. Merchant and C. R. Eidam consider the potentialities of the large-scale use of animal cell cultures for biochemical syntheses and interconversions, and N. C. Dondero is concerned with the nature and economic significance of the sheathed, slime-forming bacteria of the genus *Sphaerotilus*.

This volume is less parochial in outlook than its predecessor, and it has benefited from the effort that has been made to restore some international flavour to the series.

J. W. G. PORTER

Microbial Cell Walls

By M. R. J. Salton. (CIBA Lectures in Microbial Biochemistry, Vol. 4.) Pp. ix+94. (New York and London: John Wiley and Sons, Inc., 1960.) 28*s*.

THE CIBA Lectures in Microbial Biochemistry were established in 1955 and four of the series have now been published, the latest having been given by Dr. Salton in the spring of 1960. It deals with the isolation, electron microscopy, chemistry, synthesis and degradation of the cell walls of micro-organisms. Although the bulk of the material concerns the walls of Gram-positive bacteria, mention is also made of blue, red and brown, and blue-green algæ, fungi and yeasts, as well as Gram-negative bacteria. A wide range of information is collected in an extremely concise form and there are ample references (more than 200) to the relevant literature.

Much space is devoted to the constituents unique to bacterial cell walls—mucopeptides containing D-amino-acids, diaminopimelic acid and muramic acid; and teichoic acids consisting of polymers of ribitol or glycerol phosphates with attached carbohydrate residues and ester-linked D-alanine. The mucopeptides apparently occur in all bacterial cell walls so far examined, and it is the synthesis of this class of compound which is inhibited by such antibiotics as penicillin, bacitracin, oxamycin (D-cycloserine) and novobiocin.

The author was a pioneer in the development of methods for studying bacterial cell walls and has contributed much from a variety of aspects. The CIBA Lectures provide a welcome opportunity for an expert to give a reasoned account of his special field of interest and this volume is fully up to the standard of its predecessors.

Chromatographic Reviews

Progress in Chromatography, Electrophoresis and Related Methods, Vol. 3. Edited by Michael Lederer. Pp. viii + 187. (Amsterdam: Elsevier Publishing Co., Inc.; London: D. Van Nostrand Company, Ltd., 1961.) 50*s*.

TWO of the articles in this volume have hitherto not been published. H. Bloemendal reviews starch-column and starch-gel electrophoresis in two articles, which form a series with the first article in a previous volume on starch slab electrophoresis. Techniques and applications are adequately covered, though one wonders why the author took the trouble to write so comprehensively about the first subject when his conclusions show that he does not think much of the method. L. Reio continues a painstaking survey of the paper chromatography of phenolic and related compounds, begun in a previous volume, and gives R_F values and colour reactions of hundreds of compounds. Some of his tables contain such a heterogeneous collection of substances that the value of his article would have been enhanced by a more systematic presentation enabling one to locate a given compound. Substances which can undergo slow changes may form more than one zone on a chromatogram. This phenomenon is examined by R. A. Keller and J. C. Giddings. Z. Pučar deals fully with methods utilizing continuous electrophoresis and electrophoresis combined with chromatography. The articles by J. J. Wren are up to date and useful reviews of chromatography of lipids on silicic acid. Finally, the behaviour of inorganic ions on paper chromatograms (M. Lederer) and by ionophoresis (R. A. Bailey and L. Yaffe) are the subjects of comprehensive reviews covering progress in the past few years and complete another useful volume in this series.

R. CONSDEN

Process Chemistry

Vol. 3. Edited by F. R. Bruce, J. M. Fletcher and H. H. Hyman. (Progress in Nuclear Energy, Series 3.) Pp. vi + 474 + xii. (London and New York: Pergamon Press, 1961.) 105*s*. net.

THE first volume on *Process Chemistry* was published in the year following the 1955 Geneva Conference and contained not only a selection of conference papers revised by their authors but also a substantial number of papers specially written for it. By contrast, this third volume contains twenty-seven papers from the 1958 Conference, only one of which is marked as modified, together with a review of its two hundred process chemistry papers. It is disappointing, therefore, to find such a long delay in publication.

The book contains a reasonable selection of papers from four volumes of the official proceedings, covering the treatment of ores, the refining and production of feed materials, aqueous and non-aqueous processes for irradiated fuels and waste treatment. Some deal with operational processes, some review special aspects of the chemistry of the processes and others describe research and development work on new processes.

Much of the information represents the first open publication; the Russian papers in particular were new to the majority of delegates at the Conference. The two Conferences did in fact cover some fifteen years of work originally reported to a privileged few.

This volume does bring together under one cover a fair cross-section of the art in 1958, and is therefore of value to the library which cannot justify the expenditure on a set of the official proceedings. But it must be admitted that interested people are more likely to go to the original sources and can be kept up to date by the excellent and cheap quarterly reviews now available.

A. S. WHITE

Physical Chemistry

By Prof. Farrington Daniels and Prof. Robert A. Alberty. Second edition. Pp. x + 744. (New York and London: John Wiley and Sons, Inc., 1961.) 70*s*.

THE ancestry of this book may be traced back to Getman (1913), *Outlines of Theoretical Chemistry*, which passed through four editions by 1927, when Dr. Daniels took over. In 1955, Getman and Daniels was replaced by the first edition of the present book, which quickly became established as a leading physical chemistry text for university work in the United States. The second edition has been largely re-written and substantially expanded. The treatment is more mathematical, with emphasis on the rigorous treatment of chemical thermodynamics, the laws of which are established in the opening chapters, and quantum mechanics. This has necessitated the pruning of older and more elementary topics. New chapters on spectroscopy and statistical mechanics emphasize the thermodynamical outlook. Simple molecular orbital theory is included and there are new chapters on one-component systems and surface phenomena. Problems (836) are grouped according to difficulty at the end of each chapter and important calculations are shown in the text. A summary of the mathematical relations which might cause difficulty are included in the appendix, with values (1951) of constants (showing uncertainties) and various conversion factors. Atomic weights are based on the oxygen-16 scale (1956–57). The index seems comprehensive. The book is well produced with clear diagrams. The lucid arguments based on a logical development of the subject make the second edition of Daniels and Alberty most welcome among the modern texts giving a broad coverage of physical chemistry at university-level.

B. J. MOODY

Annual Review of Physical Chemistry, Vol. 11

Edited by H. Eyring, in association with C. J. Christensen and H. S. Johnston. Pp. vii + 587. (Palo Alto, Calif.: Annual Reviews, Inc., 1960.) 7 dollars.

THE current volume of this valuable publication reviews the literature, in most cases, to the end of December 1959. Most of the articles are concise; the first one, for example, occupies a little more than twelve pages but has 347 references. Most of the topics covered in previous volumes reappear and are carried further. Some of the articles, such as one on the quantum theory of electronic structure of molecules, will be intelligible only to specialists; others are of a more general character. The very long article on statistical theory of transport is mathematical. There are short articles on chromatography and nuclear and electronic resonance.

The article on photosynthesis will be of interest to biologists. The subject is evidently not yet fully cleared up; in particular, recent work on the pathway of carbon has received some amount of criticism. It is stated that on long manned space flights the possibility of growing algae on human wastes and using them as food is being considered. In the article on combustion and flames account is taken of high temperatures, and it is emphasized that much information about the properties of substances is still required. As for detonation phenomena, it is said that the old Chapman–Jouguet theory remains a satisfactory approach but in spite of much recent research very much remains to be done. The volume is one which physical chemists will welcome.

J. R. PARTINGTON

A Guidebook to Mechanism in Organic Chemistry

By Dr. Peter Sykes. Pp. xiii + 247. (London: Longmans Green and Co., Ltd., 1961.) 21*s*. net.

THE teaching of organic chemistry has been undergoing a revolution, and this excellent paper-backed guide-book reflects the way in which a synthesis between the experimental, factual approach essential to organic chemistry and the application of electronic theories to bring an understanding of the mechanism of reactions involving carbon compounds is being achieved at Cambridge. Much experience of lecturing and supervising undergraduates has tempered this lucid exposition of the essentials of the subject. The author has had in mind the needs of the scholarship candidate, undergraduate, technical college student and professional chemist of classical upbringing. He is rather optimistic about the sixth-form boy who will not have the necessary background of atomic and molecular orbital theory, but undoubtedly there is much here to stimulate and excite the intellectual curiosity of the more able boy.

After a brief description of valency theory in relation to organic compounds, reactivity is discussed in terms of relative electron density and the operation of steric factors. The energy changes associated with reactions and the principles underlying the investigation of their mechanism are clearly explained. The relative strengths of organic acids and bases are considered at length in terms of electronic theory and separate chapters are devoted to each of the more important types of organic reaction in such a way as to make this a most useful reference work. In addition, the printers of this most attractive book have produced (to quote the author), "that rare phenomenon, structural formulæ that are both clear and æsthetically satisfying". B. J. MOODY

Introduction to Mechanics, Matter and Waves

By Prof. Uno Ingard and Prof. William L. Kraushaar. Pp. xv + 672. (Reading, Mass., and London: Addison-Wesley Publishing Company, Inc., 1960.) 53*s*.

IN general the standard of this work, which deals with the mechanics of solids and fluids, heat and wave motion is that of the first year of an honours-degree course in physics. There is, unfortunately, a lack of balance in that two-thirds of the book is devoted to mechanics with the inevitable consequence that the remaining two topics are highly condensed and, indeed, the section on heat suffers also from an incompleteness of presentation. While applauding the determination of the authors to bring out the experimental aspects of mechanics, it seems likely that the student who possesses the knowledge of calculus and vector algebra which is required later will find the earlier discussion of force, motion and momentum frustrating, and that his interests would be better served by the omission of the more elementary illustrations in favour of an extended discussion of heat and wave motion. This apart, the treatment of mechanics is excellent, and the basic concepts of energy, and of both linear and angular momentum, are illustrated by numerous examples which range from the motion of projectiles and oscillating bodies to planetary orbits and spinning symmetrical bodies.

In the section devoted to heat the macroscopic and microscopic points of view of thermodynamics have been dovetailed into a united whole, but this commendable approach has been marred by omissions, such as the failure to present the modern definition of the absolute scale of temperature and by several errors, particularly in connexion with specific heats and with relationships involving the laws of thermodynamics. The final three chapters comprise a study of wave pulses in solids and gases, and include a treatment of both progressive and standing waves.

H. STEEPLE

Microwave Ferrites

By Dr. P. J. B. Clarricoats. Pp. xi + 260. (London: Chapman and Hall, Ltd., 1961.) 50*s*. net.

THE class of non-reciprocal microwave components which has emerged as a result of the use of magnetized ferrites has given the microwave circuit designer a new degree of freedom. Even a casual perusal of recent literature on microwave work will indicate the impact which these devices have already made, and Dr. Clarricoats's book on the subject is valuable and timely.

The subject-matter of the book includes three main topics: ferrite materials, ferrite-loaded waveguides, and ferrite components. After a brief introductory chapter, the second is mainly devoted to the structure and fundamental magnetic properties of ferrites. In the third chapter an account of the microwave properties of ferrites is given, and the fourth chapter gives a more detailed account of the loss mechanism on a physical basis, rather than phenomenologically as in the third chapter.

Chapter 5, which represents more than a third of the book, deals clearly with the very complicated problems associated with the propagation of electromagnetic waves in ferrite-loaded waveguides. Although this chapter is primarily an account of the fundamental theory, to which Dr. Clarricoats has himself made some important contributions, it is written with applications in mind, and for this reason will be particularly useful to the microwave engineer.

A final chapter gives a useful review of various non-reciprocal microwave ferrite components. In such a rapidly developing field, any review is inevitably a little out of date by the time it is published. but examples of most of the important devices developed by the end of 1959 are included. The chapter forms a very useful introduction to the extensive literature on the subject.

The book is warmly recommended as a valuable addition to the literature of microwaves.

A. L. CULLEN

Elements of Modern Physics

A Course in those aspects of Modern Physics that underline important Engineering Developments. By Paul L. Copeland and William E. Bennett. Pp. x + 507. (New York and London: Oxford University Press, 1961.) 68*s*. net.

THE publication of a volume such as this is sure evidence of the tremendous and rapid growth of atomic physics since the days of J. J. Thomson and Prof. E. Rutherford, and as the results of the more recent work done in this field are becoming increasingly incorporated into engineering practice, this book must certainly be welcomed by engineering students and also by other students of science who wish to keep abreast of modern scientific thought and developments.

The book is divided into three parts. Part 1 concerns itself with the rise of atomic physics, and develops the particular aspects of the structure of those media which seem continuous on casual inspection; it includes such topics as the kinetic theory of gases, relativity, the quantum theory and the structure of atoms. Part 2 introduces some of the ideas of wave-mechanics, while Part 3 is an introduction to nuclear physics.

To get the fullest advantage of this excellent book it is necessary that the student should have a good knowledge of classical physics and also should be well groomed with calculus and differential equations.

For those students who may wish to extend their knowledge beyond the scope of this book a useful set of references is provided at the end of each chapter, where there is also a summary and a set of searching questions.

The authors have certainly made a notable contribution to the furtherance of knowledge in this important field of modern physics, and one would hope that the book would be extensively used by many students of engineering, and others who may be interested in the phenomenal strides made in so short a time; it most surely deserves to be.

T. M. Yarwood

Proceedings of the International Conference on Theoretical Aspects of Very High-Energy Phenomena

Held at CERN, 5–9 June, 1961. Edited by J. S. Bell, F. Cerulus, T. Ericson, J. Nilsson and H. Rollnik. (Sponsored by the International Union of Pure and Applied Physics.) Pp. v+426. (Geneva: CERN—European Organization for Nuclear Research, 1961.) n.p.

The CERN conference on "Theoretical Aspects of Very High-Energy Phenomena" was held in connexion with present thinking on possible super high-energy accelerators for the post-1970 period. The report comprises about 40 papers mostly devoted to extrapolations of present-day ideas to higher energies than are at present available, but not, in general, directed to specific accelerators. The present report is not too rich in theoretical reasons for proceeding to higher energies, but this is perhaps not to be expected—in his summary lecture Prof. van Hove refers to the well-known drastic limitation of our power of imagination.

The report comprises the following sections: weak interactions; electromagnetic interactions; experimental results (including cosmic ray and CERN *PS* results); statistical model; diffraction theory; one-meson exchange; dispersion theory and Mandelstam representation; accelerators. The section on electromagnetic interactions is largely concerned with the electron storage rings building and projected at Frascati and Stanford; in addition to electron–electron colliding-beam experiments providing a sensitive test of quantum electrodynamics at high energies, electron–positron annihilation gives a large field of interesting and significant events as set out in the paper by Gatto. Higher-energy protons should provide tests of theories of weak interactions (particularly by giving neutrino and muon beams) and should help to elucidate diffraction scattering and the asymptotic behaviour of cross-sections at high energies, on which so much theoretical speculation is at present bent.

R. G. Moorhouse

Symposium of Plasma Dynamics

Edited by Francis H. Clauser. (Sponsored by the Air Force Office of Scientific Research. Prepared under the auspices of the National Academy of Sciences.) Pp. ix+369. (London: Pergamon Press; Reading, Mass.: Addison-Wesley Publishing Company, 1960.) 84*s*. net.

The symposium at Woods Hole, Massachusetts, in June 1958 boasted an impressive list of participants almost exclusively from the United States. No formal papers were given, but rather a series of discussions with introductory talks at the beginning of each session.

The chapters on the experimental investigation of plasma properties show the beginnings of many studies on waves in plasmas, the interaction of electron beams with ionized media, shock-waves in conducting media in the presence of a magnetic field in addition to diagnostic work on transient plasmas in a variety of geometries.

The theoretical contributions discuss instabilities with great clarity, and the heating and confinement of plasmas. Continuum and particle approaches are reviewed and compared, and the limits of their applicability considered.

A short chapter on aerodynamic effects when a plasma streams through a magnetic field together with longer contributions on extra-terrestrial magneto-hydrodynamics conclude the symposium. Interesting accounts of such phenomena in the solar system appear, and cosmic magnetic fields are reviewed also. Their influence on interstellar material has repercussions over a wide range of astrophysics. A vigorous debate on the simulation of galactic phenomena in the laboratory is reported, in which one conference aim—the frank expression of conflicting views—is realized to the full. This book presents clearly the concepts of modern plasma dynamics, forming a good introduction to the subject, complete with a valuable bibliography. It cannot, naturally, be taken as a summary of the present state of the art.

P. F. Little

Yearbook of Astronomy 1962

Edited by J. G. Porter, in association with Patrick Moore. Pp. viii+216. (London: Eyre and Spottiswoode (Publishers), Ltd., 1961.) 15*s*. net.

This book is designed not so much for the amateur with his own telescope and observing programme but for the very many who can observe only with the naked eye, binoculars or small telescopes. To this end it succeeds admirably, and we look forward to seeing the *Yearbook* maintaining the high standard of this issue for many years to come.

The *Yearbook* may be divided into two sections. The first section provides a set of "Monthly Notes", mainly concerned with planetary observations and a set of star charts. The "Monthly Notes" are augmented by notes on various phenomena of interest, such as meteor showers, zodiacal light, etc. The star charts are arranged so that the stars move from the positions in one chart to the positions in the following chart in a period of 2 hr. This section is completed by notes on eclipses, occultations, comets, meteors, minor planets and selected events for 1963.

The second section contains thirteen short articles on various aspects of astronomy. Each article is written by an author experienced in the field covered by the article. The shortness of the articles is compensated by including a fairly comprehensive reading list so that if any reader is sufficiently stimulated by a given article he can carry on his reading by choosing a suitable book from the list.

A list of astronomical societies, a comprehensive glossary of astronomical terms and a list of selected interesting telescopic objects conclude the book. The *Yearbook* should form a very useful addition to the shelves of any amateur astronomer.

D. McNally

Relativity for Engineers and Science Teachers

By Laurence H. A. Carr. Pp. vi+52. (London: Macdonald and Co. (Publishers), Ltd., 1960.) 12*s*. 6*d*. net.

THIS little book is a commendably brave, and, one must add, successful attempt by the author to convince students, hitherto perhaps a little timorous of getting to grips with the theory of relativity, that the principles, when shorn of the complex mathematical treatment, are not so formidable after all.

Although the full subject of relativity consists of two separate theses, the special theory dealing with two bodies in uniform relative motion and the general theory which concerns the movement of bodies under the influence of a permanent accelerating force, it is only the former which is dealt with here.

The opening chapter is given to recapitulating the basic theory of what is regarded as the classical mechanics, while the rest of the book is devoted to the modifications introduced by the theory of relativity and which are necessary to bring experimental data and theory into harmony.

The well-known Michelson–Morley experiment was, of course, the crisis in physics which sparked off the theory of relativity by Einstein in 1905, and the author of *Relativity for Engineers and Science Teachers* deals with this very well in a separate chapter, in which he brings out clearly the value of the "contraction formula" of Lorentz–Fitzgerald, namely,

$$\sqrt{1 - \frac{v^2}{c^2}},$$

which occurs throughout the theory of relativity.

At the end of the book there is an extremely useful summary of the conclusions reached, and this should be most helpful.

Altogether the book is well thought out and excellently done, and students and teachers alike should find it stimulating, informative and understandable.

T. M. Yarwood

Electron Microscopy in Anatomy

Proceedings of a Symposium held by the Anatomical Society of Great Britain on the Ultra-Structure of Cells. Pp. viii+288. (London: Edward Arnold (Publishers), Ltd., 1961.) 50*s*. net.

THIS is an interesting and genuinely useful symposium. The importance of the various chapters varies considerably, but there are several contributions of outstanding value, especially those on the myelin sheath of nerves, the 'unit membrane', and the secretory processes of the pancreatic exocrine cell. These chapters provide very convenient summaries of the present state of knowledge.

Twenty years from now it will be interesting to look back on such a book as this. Has the early work in electron microscopy proceeded along the most fruitful lines? It is too soon to judge. The techniques used in the preparation of tissues seem to be rather empirical. It is almost as though we had not profited from the work of such men as Alfred Fischer, W. B. Hardy, and Gustav Mann, who sought, six decades ago, to place the technical methods of light microscopy on a firmer, less empirical basis. There is a scramble to be the first to 'see' new things, but scarcely enough effort to ensure that what is exhibited in our micrographs bears any close relationship to what was present in life. Perhaps this phase was inevitable: perhaps we are now emerging from it into a more hopeful future. This book gives a useful indication of how far we have gone and where we are likely to go next.

J. R. Baker

Industrial Research in Britain

Advisory Editor: A. W. Haslett. Fourth edition. Pp. 461. (London: Harrap Research Publications, 1962.) 84*s*. net.

IN the fourth edition of *Industrial Research in Britain* Mr. A. W. Haslett succeeds Dr. Percy Dunsheath as advisory editor, and additional sections for sponsored research organizations, scientific attachés, data-processing services, translations of Soviet technical and scientific periodicals and technical libraries have been introduced. The existing sections have been completely revised and some are presented in a new format. Sir Harry Melville outlines the part which the Government plays in civil research and development and in the technical information services of Britain. Mr. A. F. H. Baylis contributes an article on careers in professions associated with industrial research which is both admirable in itself and supported by an excellent bibliography.

In the sixteen years since the book was first published its character has been transformed, and although the price has been quadrupled it now supplies what the first edition could scarcely claim to do—a comprehensive reference book on industrial research in Britain generally. Such points of criticism as may be advanced are in matters of detail, doubtless due to oversight, and chiefly in relation to publications. The section dealing with research activities of Government departments and statutory bodies fails to give the complete picture of Government organization that might have been expected; the Nature Conservancy is the only one of the Research Councils not mentioned and even in a volume dealing with industrial research the omission is invidious as well as unjustified. Although the pamphlet *Government Organization in the Civil Field* is out of date, its existence might have been mentioned. Similarly, the section on industrial research in universities should fittingly have mentioned the publication put out by the British Council for the Department of Scientific and Industrial Research entitled *Scientific Research in British Universities*. Surprisingly, the section dealing with periodicals omits *The New Scientist* although including older periodicals of the same general scientific or technical character.

R. Brightman

(*Continued from page* 42)

over large regions of the temperate zone ionosphere as well as the auroral zones. Such heat input can modulate[5] the temperature at 150 km. by hundreds of degrees K. For the following calculation put $\delta T_0 =$ 300° K. and $T_0 =$ 500° K. originally. Then n_0 changes by 60 per cent due to change in scale height at the 0 level. The percentage change in n will increase with height until it is more than 200 per cent at 650 km. This compares favourably with the increase by a factor of 2·5 of the density at 656 km. deduced from the orbital acceleration[1] of Satellite 1958 β2 (cf. ref. 3).

It is concluded on the basis of the crude analysis above that joule heating of the lower reaches of the ionosphere (100–250 km.) is a major factor in modulation of thermospheric densities. Other factors would be the absorption of radiation from the Sun giving an additional day–night effect[6] superimposed on the *Sq* variation, and the generation of heat by corpuscular radiation impinging on the ionosphere from the magnetosphere. While the energy for the *Sq* variation is thought to be derived from tidal oscillation of the upper atmosphere, the energy for the magnetic disturbance variation is due to that portion of the radiation of the Sun which takes a day or so to come to the Earth. The magnitude of the density fluctuations dependent on magnetic disturbance should increase with height and with proximity to auroral regions. It is suggested that thermospheric densities as deduced from the orbital acceleration of a satellite should correlate well with the local magnetic *K* index at the latitude and longitude of its perigee.

A Source of Energy for the Ionosphere

THE heat requirement of the equatorial and temperate zone ionosphere is normally about 2 × 10^{10} cal. sec.$^{-1}$ (cf. Johnson[1]). This is because of the loss of heat downwards due to a temperature gradient of about 10° K. km.$^{-1}$ between 100 and 200 km. altitude. It is the purpose of this communication to suggest that joule heating by ionospheric electric currents can supply heat in this quantity. Current of density (j) causes joule heating at the rate Q given by j^2/σ_3, where σ_3 is the Cowling conductivity.

Consider first those ionospheric currents causing the quiet solar daily variation (*Sq*) of the geomagnetic field. Their intensity[2] is about 10^4 amp. per degree of latitude. Assuming they flow in a height range of 50 km. in a quiet ionosphere in which $\sigma_{3(\text{average})} \approx 4 \times 10^{-14}$ E.M.U., $Q(Sq)$ is about 10^{-8} erg cm.$^{-3}$ sec.$^{-1}$. Over the whole globe this amounts to about 10^{10} cal. sec.$^{-1}$.

Secondly, there are the currents which contribute to the disturbance daily variation (*Ds*) of the geomagnetic field. Average currents in the auroral zone during the Second International Polar Year[3] taken in conjunction with a ten-fold increase of ionospheric conductivity implies a peak $Q(Ds$, auroral) value of 10^{-5} erg cm.$^{-3}$ sec.$^{-1}$ at 150 km. altitude and averaging about 10^{-6} erg cm.$^{-3}$ sec.$^{-1}$ throughout the 100–200 km. height-range[4,5]. An estimate of $Q(Ds$, low latitude) is difficult to make, for the appropriate ionospheric conductivity during disturbance is not known. However, $Q(Ds$, low latitude) is assumed to be of the same order as $Q(Sq$, low latitude). Assuming the auroral heating region extends 10,000 km. around the two auroral zones at any given instant, the total average flux from them is about 2 × 10^{10} cal. sec.$^{-1}$.

Thirdly, there is probably a contribution from the storm time (*Dst*) variation of the geomagnetic field supposed here to be due to currents flowing in the ionosphere with an average strength of about 10^4 amp. per degree of latitude (cf. Figs. 23. 24 of Chapman and Bartels[2]). Assuming no great change in average conductivity over the whole globe, $Q(Dst)_{\text{av}} \approx Q(Sq)$.

There will be a flux of heat from auroral regions to other parts of the ionosphere. Johnson[1] has shown that convection is far more important than conduction in this process. Heating of the auroral ionosphere will cause distortion of the constant pressure surfaces so that at 200 km. altitude such a surface can change height by as much as 50 km. (refs. 4 and 5). The horizontal gradient of pressure is balanced by the Lorentz force $j \times H$, where H is the (near vertical) geomagnetic field. This Lorentz force was not taken into account in ref. 1. This pressure gradient can have winds of more than 100 msec.$^{-1}$ associated with it[4]. Such winds could convect heat from the auroral zones to distances of 10,000 km. in times of order 10 hr., and could produce all the heat requirements of the lower latitude ionosphere[1]. Any conduction of heat from the auroral zones would proceed most rapidly at the higher ionospheric levels, to come downwards in other regions of the globe.

Now $Q(Ds)$, and $Q(Dst)$, may range over some orders of magnitude. However, this point is uncertain for it is not known whether an increase in j is accompanied by an increase of σ_3 to leave $Q(Ds)$ substantially unaltered. Since magnetic disturbance (δH) is approximately proportional to j, an increase of a factor 10 of δH above average implies a 100-fold increase of σ_3 (that is, 1,000 times a quiet low latitude value) to keep $Q(Ds)$ constant. The implied electron densities are then 10^8 cm.$^{-3}$, that is, a factor of 50–100 larger than can reasonably be expected over large regions. Thus it is reasonable that $Q(Ds)$ increases at least by a factor 10 above average for the very large magnetic disturbance. Moreover, magnetic disturbance is generally more widespread when it is more intense. Hence at these times the flux available to the global atmosphere is greatly enhanced, perhaps by a factor 100 above normal.

A major source of heat for the ionosphere is joule heating by those electric currents flowing in it to cause geomagnetic variations (separated above into *Sq*, *Ds*, *Dst*). It is suggested that heat from this source is normally sufficient to account for the heat flux in the low-latitude ionosphere. At times of very large magnetic disturbance the available heat, due to *in situ* heating and flux from the auroral zones, can be at least a factor 10 above average.

PHYSICS

A Simple Low-Noise Low-Frequency Transistor Amplifier

The properties of the amplifier to be described are entirely due to the type of transistor used, and the purpose of this communication is to report on its suitability for the amplification of electro-physiological wave-forms, particularly those originating in the brain. Of the commonly recorded physiological potentials, the electroencephalogram (EEG) presents the most difficulties because of the low voltage (10–1,000 μV.) and low frequency (1–50 c./s.) of its components. Recordings are usually obtained from electrodes on the scalp which give an output impedance of the order of 10,000 ohms. Hitherto, transistors have been unsuitable for amplifying these potentials direct because their intrinsic noise at low frequencies was too high and because the input impedance of the simpler circuit configurations was too low—about 1,000 ohms in the common emitter mode.

However, a new type of planar silicon transistor (Texas Instruments Inc., Type No. 2*N*929), designed to have low noise, has recently become available. Furthermore, because of the low currents at which it can be operated, it has a high input impedance when used in the common emitter mode. The circuit of Fig. 1 probably does not represent the best that can be devised for this transistor, but it gives a useful performance as an amplifier, providing a gain of about 30 and presenting an input impedance of about 200,000 ohms for a transistor power consumption of 10 μamp. at 3 volts.

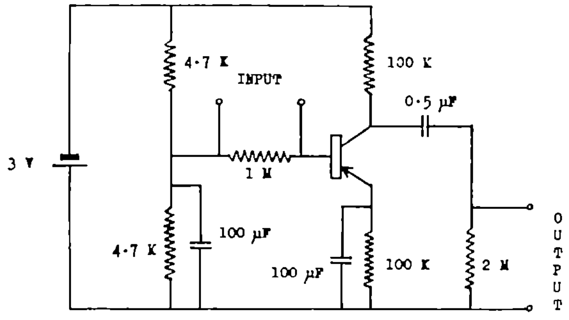

Fig. 1

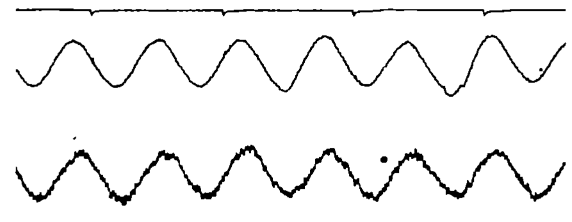

Fig. 2. Upper trace, 1-sec. time marker; middle trace, 5-μV. peak-to-peak input at 1·5 c./s. from a source impedance of 100 ohms, via transistor amplifier; lower trace, same input via EEG amplifier

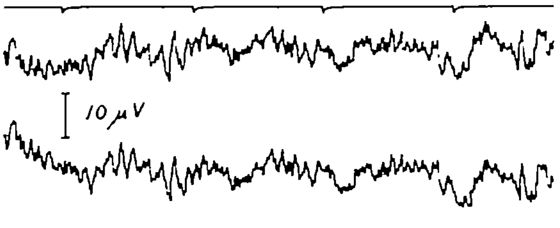

Fig. 3. Upper trace, 1-sec. time marker, middle trace, EEG signal via transistor amplifier; lower trace, same signal via standard EEG amplifier

The noise-level is illustrated in Fig. 2. The middle trace shows the output from the transistor amplifier (further amplified by a conventional EEG channel working at low gain) for an input of 5 μV. peak-to-peak at $1\frac{1}{2}$ c./s. derived from a source impedance of about 100 ohms. The lower trace shows the same signal amplified by another channel of the same EEG machine. The transistor amplifier has a noise-level of appreciably less than 1 μV. referred to the input. This is better than that obtained by an average EEG amplifier of which the lower trace is a typical example. Fig. 3 shows a low-voltage EEG signal derived from a pair of standard padded electrodes on the scalp and recorded by both methods at a sensitivity of 10 μV./cm. These traces suggest that the noise-level of the transistor amplifier is not sensibly worsened by the higher output impedance of ordinary EEG electrodes—about 8,000 ohms in this case.

A floating single-ended amplifier stage of this kind, with one side of the power supply earthed, has an in-phase rejection ratio of zero. However, the low-power requirements of these devices, which make it possible to use power supplies completely isolated from earth, open up new possibilities for the attainment of very high in-phase rejection ratios. Work is in hand to devise practical arrangements.

X-Ray Yields from Elements in the Range Beryllium to Aluminium

Absolute measurements have been made, it is believed for the first time, of the *K* X-ray quantum yields resulting from electron bombardment of solid targets containing the elements beryllium, boron, oxygen and fluorine. For beryllium and boron 99 per cent pure targets were used while beryllium oxide and lithium fluoride were used for the oxygen and fluorine yields; corrections were applied for electron and X-ray absorption in the beryllium and lithium respectively. The yields from carbon (graphite) and aluminium targets have also been measured.

The X-ray count-rate was determined by pulse height analysis of the output from a gas-flow proportional counter filled with argon plus 2·5 per cent carbon dioxide. An essential feature of this counter was the provision of a very thin nitrocellulose entrance window capable of withstanding a pressure difference of one atmosphere: for the beryllium measurements this was only about 1000 Å. thick. After subtraction of the continuous radiation from the pulse height distribution, the measured *K* radiation count-rate was corrected for instrumental effects, such as the variation of counter efficiency with X-ray wave-length. A range of incident electron energies between 500 and 30,000 eV. was used on each target; the current was independently controlled and was varied between 5×10^{-10} and

8×10^{-7} amp. The diameter of the irradiated area of the target was less than 50μ.

The observed variation of the X-ray yield with electron energy is in excellent agreement with Archard's[1] theoretical predictions. The absolute values of the yields, other than that from beryllium, are 5–15 per cent higher than those given by Archard's theory, provided that the latter is modified by using Burhop's[2] formula for the fluorescence yield; the beryllium yield is about half that predicted. The carbon and aluminium yields are about half those reported by Dolby[3].

Apart from their significance as a test of the theory of X-ray emission from solid targets, the results indicate that X-ray microanalysis of all elements of atomic number higher than 3 is now theoretically and technically feasible. A full account and discussion of the work is being prepared for publication elsewhere.

Thanks are due to Dr. T. E. Allibone, director of the Laboratory, for permission to publish this communication.

Errors involved in using the Rayleigh Equation for Interpretation of Light-Scattering Data beyond its Normally Accepted Limits

FOR a non-absorbing, spherical particle which is very small compared with the wave-length of the incident light, the intensity of the scattered light may be calculated from the Rayleigh equation, which assumes that the particle may be represented by a single vibrating electric dipole. The limit normally associated with its use is a radius, r, of $0{\cdot}05\lambda$, where λ is the wave-length of the radiation in the medium surrounding the particle. This corresponds to a value of the size parameter $\alpha = 2\pi r/\lambda$ of 0·3 approximately. When the particle is comparable in size to the wave-length of the incident light, account must be taken of the electric multipoles and the induced magnetic multipoles. The solution of this problem was originally proposed by Mie[1] for any values of α and m, where m is the refractive index of the particle relative to that of the medium, and involves complicated expressions which are laborious to evaluate.

However, in certain cases this can be avoided[1]. When the scattering functions calculated from the Rayleigh equation for $\alpha > 0{\cdot}3$ are compared with published values obtained using the Mie formulæ, it is found that the errors involved in using the Rayleigh equation are not significant for values of m in the region of 1·5 and for $\alpha < 1{\cdot}0$. The limit beyond which use of the Rayleigh equation introduces an appreciable error is dependent on the value of m as illustrated for the scattering coefficient K in Fig. 1. (Similar calculations, but in a more restricted range of m values, have been reported earlier[8].) This is also shown for the total intensity at 90° in Table 1 using the limited number of reliable Mie values available.

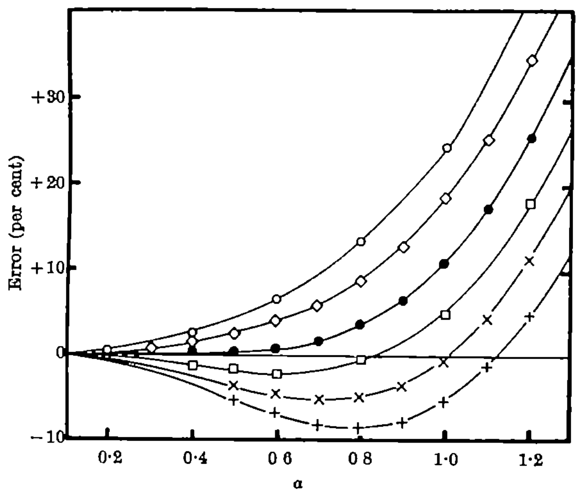

Fig. 1. Percentage error involved in using the Rayleigh equation to evaluate the scattering coefficient K

(Reference is given to the sources of Mie values used in the calculations.) ○, $m = 1{\cdot}25$ (ref. 3); ◇, $m = 1{\cdot}38$ (refs. 4 and 5); ●, $m = 1{\cdot}44$ (refs. 4 and 5); □, $m = 1{\cdot}55$ (refs. 4 and 6); ×, $m = 1{\cdot}65$ (ref. 7), +, $m = 1{\cdot}75$ (ref. 7)

Table 1. PERCENTAGE ERROR INVOLVED IN USING THE RAYLEIGH EQUATION TO EVALUATE THE TOTAL INTENSITY OF SCATTERED LIGHT AT 90°

(Reference is given to the sources of Mie values used in the calculations)

α	$m = 1{\cdot}33$ (ref. 4)	$m = 1{\cdot}44$ (ref. 4)	$m = 1{\cdot}55$ (ref. 4)	$m = 1{\cdot}75$ (ref. 8)
0·5	+ 2·68	+ 0·37	− 1·69	—
0·6	+ 4·41	+ 1·28	− 1·74	− 6·37
1·0	+22·5	+15·1	+ 8·78	− 1·26
1·2	+45	+37	+29	+17·2

Clearly the limit to which the Rayleigh equation can be usefully applied in the range $1{\cdot}3 \leqslant m \leqslant 1{\cdot}75$ is higher than that usually quoted. Fortunately, many of the colloid systems of current interest lie in this range.

GEOLOGY

Study of Natural Glasses through their Behaviour as Membrane Electrodes

THE low-temperature chemical alteration of natural glass occurs in two stages: an initial stage in which it remains glassy but absorbs as much as 6 per cent water[1], and a final stage in which devitrification to clay minerals, with release of silica, occurs[2,3]. During the first stage the composition of the glass may change, with gain of K_2O and water and loss of Na_2O (Smith, R. L., personal communication). This change is due to ion exchange.

The traditional method of examining ion exchange is to equilibrate the powdered material with a series of solutions containing the ions of interest, and to analyse the chemical changes in the glass and/or solution. A new method is described here which is rapid and accurate for suitable materials, such as the natural glasses. This method consists of forming a membrane electrode of the ion-exchanger and determining the electrical potential of this against a reference electrode, in solutions of the exchangeable ions.

The potential of a glass membrane electrode in an aqueous solution of two salts has been shown by Nikolsky[4] to be dependent on the activities of the (univalent) exchangeable ions $[A^+]$ and $[B^+]$ according to equation (1).

$$\text{e.m.f.} = C_{AB} + \frac{RT}{\mathcal{F}} \ln \left([A^+] + K_{AB}[B^+]\right) \qquad (1)$$

Here K_{AB} is the mass action exchange constant for the exchange

$$AX + B^+ = BX + A^+ \qquad (2)$$

and X^- denotes a negative site on the glass. Equation (1) was later shown to be true only when the adsorbed ions form an ideal solution on the glass. More general equations are, first, that suggested by Eisenman *et al.*[5]:

$$\text{e.m.f.} = C_{AB} + \frac{RT}{\mathcal{F}} \ln \left([A^+]^{1/n_{AB}} + K_{AB}{}^{1/n_{AB}} [B^+]^{1/n_{AB}}\right)^n \qquad (3)$$

where n_{AB} is an empirical constant near unity, and, secondly, that given by Garrels *et al.*[6]:

$$\text{e.m.f.} = C_{AB} + \frac{RT}{\mathcal{F}} \ln \left(\frac{[A^+]}{\lambda_{AX}} + K_{AB} \frac{[B^+]}{\lambda_{BX}}\right) \qquad (4)$$

In equation (4), λ_{AX} and λ_{BX} are the rational activity coefficients of the adsorbed ions. Garrels *et al.*[6] further state that glass and mineral solid binary solutions frequently form 'regular solutions', so that the activity coefficients of the binary solution are related to the mole fractions (N) by the simultaneous equations:

$$\lambda_{AX} = \exp\left(\frac{B_{AB}}{RT} N^2_{BX}\right) \qquad (5a)$$

$$\lambda_{BX} = \exp\left(\frac{B_{AB}}{RT} N^2_{AX}\right) \qquad (5b)$$

where B_{AB} is an empirical constant.

These same authors have also derived equations for the bi-ionic potential resulting from the combination of one univalent and one bivalent cation, and from two bivalent cations. These equations are:

$$\text{e.m.f.} = C_{CD} + \frac{RT}{2\mathcal{F}} \ln \left(\frac{[C^+]^2}{\lambda_{C_2X_2}} + K_{CD} \frac{[D^{++}]}{\lambda_{DX_2}}\right) \qquad (6)$$

and

$$\text{e.m.f.} = C_{EF} + \frac{RT}{2\mathcal{F}} \ln \left(\frac{[E^{++}]}{\lambda_{EX_2}} + K_{EF} \frac{[F^{++}]}{\lambda_{FX_2}}\right) \qquad (7)$$

A simple and accurate means of determining both the ion exchange constant K and the type of solid solution that the adsorbed ions form is given by these equations.

To make an electrode, a 1-cm. × 1-cm. chip of a natural glass was ground flat on one side and finished with -900-mesh abrasive. This side was cemented with Canada balsam to a glass slide and the chip was ground to about 0·05 mm. thickness and finished with -900-mesh abrasive. The slide was heated and the glass membrane gently slid off into a small beaker. Successive rinsings with xylene removed the adhering balsam and the chip was dried and transferred to a flat paper surface. A 10-cm. length of 6-mm. glass tubing was ground flat on one end. This end was heated and coated with thermoplastic cement; while still hot the coated end was lowered on to the glass membrane so that the membrane was sealed to the tube around the edge without allowing the plastic to coat the centre of the membrane. The tube was then filled with 0·01 M hydrochloric acid; a silver wire coated with silver chloride was inserted, and the open end of the tube was sealed. It is necessary to seal the membrane carefully in order to make the membrane itself the lowest resistance electrical path between the internal solution and whatever external solution surrounds the electrode. This method is similar to that of C. E. Marshall[7] except for the use of considerably thinner membranes.

The completed electrode is placed in a solution with a saturated potassium chloride–calomel, or a silver–silver chloride reference electrode that includes a saturated potassium chloride salt bridge. The potential between these electrodes was measured with a high impedance electrometer. The solution is maintained at 25·00 ± 0·05° C. and stirred magnetically. The electrode is first placed in a solution of known concentration of a single cation, as the chloride, and the potential measured as soon as equilibrium has been attained. Anions have no effect on the potential except for a contribution to the ionic strength which influences the activity coefficients of the cations. Aliquots of successively more concentrated standard solutions of a second chloride are added in order to vary the cation ratio as widely as possible. After each addition the equilibrium electrical potential is measured and recorded along with the composition of the solution.

The activities are calculated from the known concentrations of the cations in solution by using single ion activity coefficients from the Debye–Hückel equation for solutions more dilute than 0·01 molar. For more concentrated solutions the activity coefficients are derived on the assumption that $\gamma_{\pm\mathrm{KCl}} = \gamma_{\mathrm{K}^+} = \gamma_{\mathrm{Cl}^-}$, and therefore that:

$$\gamma_{M^+} = \frac{\gamma^2_{\pm M\mathrm{Cl}}}{\gamma_{\pm\mathrm{KCl}}}, \text{ and } \gamma_{M^{++}} = \frac{\gamma^3_{\pm M\mathrm{Cl}_2}}{\gamma^3_{\pm\mathrm{KCl}}}$$

From the activities and the electrical potential measurements the appropriate electrode equation (4), (6) or (7) is solved in combination with equation (5) by the curve-fitting method shown in Garrels *et al.*[6]. The solution yields the constants of the electrode equation, as, for example, in equation (4), C_{AB} and K_{AB}, and the value of B_{AB} of equation (5).

The exchange constants found by this method for two rhyolytic obsidians and a tektite are shown in Table 1. The obsidians differ in that one is a lava, the other a welded tuff.

Chemical changes due to the reaction of water with natural glass in two extreme situations may be calculated. In case A the mass of glass reacting is negligible compared with the mass of the water. In case B the mass of water is negligible. These are approximated in the geochemical history of water flowing through a freshly deposited bed of vitric tuff. Initially the water composition will be affected by the glass as in case B, but as large volumes of water continue to flush through the final composition of the glass shards will approach that in case A. For

the obsidian in Table 1, the relevant equations are (considering only Na^+, K^+ and H^+):

$$\frac{[HX]\ [Na^+]}{[NaX]\ [H^+]} = 3{\cdot}2;\quad \frac{[HX]\ [K^+]}{[KX]\ [H^+]} = 1{\cdot}3;$$

$$\frac{[KX]\ [Na^+]}{[NaX]\ [K^+]} = 2{\cdot}5$$

The results given in Table 2 are in good agreement with analyses of hydrated glass in tuffs (4) and with compositions of ground waters in beds of vitric tuff[8].

Table 2. CHANGES IN SODIUM, POTASSIUM AND HYDROGEN CONTENT OF AN OBSIDIAN DUE TO ION EXCHANGE WITH A GROUND WATER. CASE *A*, MASS OF WATER ≫ MASS OF GLASS; CASE *B*, MASS OF WATER ≪ MASS OF GLASS

	Glass composition (mole per cent)		
	Initial	Final, case *A*	Final, case *B*

K_2O	3·77	5·34	3·77
H_2O as H^+ on exchange sites	0·001 (est.)	0·68	0·001

	Water composition (molal)		
	Initial (assumed)	Final, case *A*	Final, case *B*
Na^+	1×10^{-4}	1×10^{-4}	$1{\cdot}6 \times 10^{-4}$
K^+	1×10^{-4}	1×10^{-4}	$5{\cdot}2 \times 10^{-5}$
H^+	1×10^{-5}	1×10^{-5}	$1{\cdot}2 \times 10^{-8}$

The technique described can also be used to study ion exchange on minerals and as a quick way of determining the usefulness of artificial glasses for glass electrodes without changing the composition by heating during the blowing of bulbs. Since the chemical durability of a glass is related to the ease of cation–hydrogen ion exchange, this technique also could be used as a test of durability.

This work was partially supported by a National Science Foundation Graduate Fellowship at Harvard University, and was carried out under the direction of Prof. R. M. Garrels, whose guidance is gratefully acknowledged. I am also indebted to C. L. Christ, U.S. Geological Survey, for critical discussion and advice in the preparation of the manuscript.

Publication has been authorized by the Director, U.S. Geological Survey.

CRYSTALLOGRAPHY

New Compound in the System $CaO–Al_2O_3–CaF_2$

I WISH to report a new compound in the system $CaO–Al_2O_3–CaF_2$. The compound is thought to be $3CaO.3Al_2O_3.CaF_2$ and was discovered simultaneously in separate but related fields of work. One investigation was concerned with the effect of additions of calcium fluoride to the system $CaO–Al_2O_3$. The other investigation was concerned with the effect of calcium fluoride on the important cementitious compound monocalcium aluminate. Quench-furnace techniques, X-ray methods, and optical methods were used in this work.

The compound has also been identified in aluminous slags obtained from phosphorus-production furnaces.

Chemical analysis of the compound for calcium, aluminium and fluorine are compared in Table 1 with theoretical figures. Difficulties of analysis were encountered with the fluorine determinations.

Table 1. CHEMICAL ANALYSIS OF THE NEW COMPOUND

	Found (per cent)	Theoretical (per cent)
CaO	39·73	40·63
Al_2O_3	53·81	55·39
F	6·05	6·88

Weissenberg and rotation X-ray photographs were taken of a single crystal of the compound. From these the unit cell was determined as being hexagonal with:

$$a = b = 17{\cdot}29\ \text{Å}.,\ c = 7{\cdot}01\ \text{Å}.$$

The density, measured by the flotation method, was found to be 2·96 gm./cm.^{3}; the theoretical density, ρ_c = 3·03 gm./cm.^{3}. Powder photographs, taken using a Guinier-type focusing camera, were indexed using the data obtained from the single crystal work and the results are shown in Table 2.

Fig. 1 shows a thin section of the compound viewed with crossed nicols at a magnification of 35 times. It was found to be uniaxial negative with refractive indices ω = 1·628, ε = 1·618.

Besides the melting point, which is 1,507 ± 2° C., a few measurements of its cementitious properties have been made. The compound was ground to a specific surface of 2,716 cm.^{2}/gm.; compressive strengths of

0·30	7	20	30	10
0·35	29	45	48	0
0·50	64	0	—	

vibrated mortar cubes and setting times were then determined by the methods laid down in British Standard 915, 1947.

It is interesting to note that although the final set was 19 hr. when the water to cement ratio was 22 per cent, the compressive strength after 24 hr. was sufficient to pass the British Standard for aluminous cement. X-ray measurements have shown that hydrates $4CaO.Al_2O_3.13.H_2O$ and $CaO.Al_2O_3.10H_2O$ are formed.

I thank Dr. J. A. Baldrey and Dr. M. W. Dougill for the X-ray data and Mr. A. Wood for the cement testing.

RADIATION CHEMISTRY

Electron and Corona Bombardment of Polyethylene

The adverse effects of corona discharges on polyethylene have been known for some years. Damage to the polymer has variously been ascribed to ionic bombardment[1], electron bombardment[2] and to chemical and thermal effects.

It has recently been observed that corona discharges in moist air can produce oxalic acid crystals on a polyethylene surface[3]. When a charged steel sphere at 20 kV. (r.m.s., 60 cycle a.c.) was placed on a polyethylene surface for 20–120 hr., a ring of oxalic acid crystals was formed around the point of contact; the radius of the ring could be varied by changing the applied voltage. It was suggested that electrons from the sphere travelled along the lines of force of the applied field, and calculations based on this concept gave ring diameter values in accordance with the experimental results.

In experiments with stretched polyethylene films[4], electrical stresses of 200 V./mil were applied in ambient atmospheres of air at rather high humidities. Oxalic acid crystals formed in every case in a ring surrounding the electrodes and were more sharply defined in areas where corona intensity was least severe. The acid was not formed in a nitrogen atmosphere, nor in dry air. Corona resistance was greater at high humidities through the formation of a conducting surface layer which graded the electric field.

Because of the increasing interest in the use of radiation cross-linked polyethylene for electrical purposes, it seemed desirable to show whether the high-energy electrons used for cross-linking had the same effects as a corona discharge in producing oxalic acid. Studies of the γ-ray and neutron irradiation of polyethylene have shown that oxalic acid is not formed[5].

Moulding powder granules of low-density polyethylene (type *M*101, Monsanto Chemicals, Ltd.) were irradiated in moist laboratory air with electrons from a Van de Graaff electrostatic particle accelerator. The usual cross-linking dose of 20 Mrads was delivered in 1-Mrad increments to prevent excessive rise in temperature, and an initial electron energy of 2 MeV. was used to ensure virtually uniform dosage through the granules. In another experiment, using less-severe conditions, a dose of 2 Mrads was delivered in 60 increments using 0·5 MeV. electrons.

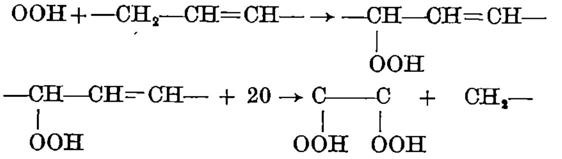
Extraction of the granules with hot water was followed by evaporation to dryness, and the residue in each case was warmed with a small crystal of diphenylamine, which forms a condensation product with oxalic acid. This can be detected by the blue colour of its alcoholic solution, giving a detection sensitivity of 10 μgm. However, in no experiment was any acid found on the polymer surface; attempts to detect acid in the bulk of the polyethylene were unsuccessful as diphenylamine is apparently destroyed when warmed with the polymer and no colour is formed even in the presence of large amounts of added oxalic acid.

It is possible that oxalic acid was formed and as rapidly destroyed through scission of the C—C bonds by electrons[6]. No reference to the effect of electrons on solid oxalic acid has been found, but such scission would yield entirely volatile products. A 2-gm. sample of the solid acid dihydrate lost only 0·3 per cent of its weight on receiving a 20-Mrads dose of 2-MeV. electrons, and was apparently unaffected by the treatment apart from acquiring a light buff colour.

The following mechanism has been proposed[3] for the formation of oxalic acid by a corona discharge in moist air:

$$O_2 + e \rightarrow O_2^{-}$$

$$O_2^{-} + H_2O \rightarrow OH^{-} + .OOH$$



$$OOH + \text{—CH}_2\text{—CH=CH—} \rightarrow \text{—}\underset{\substack{|\\ OOH}}{\text{CH}}\text{—CH=CH—}$$

$$\text{—}\underset{\substack{|\\ OOH}}{\text{CH}}\text{—CH=CH—} + 2O \rightarrow \underset{\substack{|\\ OOH}}{\text{C}}\text{——}\underset{\substack{|\\ OOH}}{\text{C}} + CH_2\text{—}$$

It depends on an initial combination between molecular oxygen and electrons of low energy produced by ionization in the polymer. It is probable that under the bombardment conditions of the present experiments such low-energy electrons were produced in insignificant numbers. As the mechanism also relies on the presence of transvinylene groups in the polymer, it is suggested that polyethylenes with a small number of such groups might be more corona-resistant than others. It has been found that 'Rigidex *R*101/2' (British Hydrocarbon Chemicals, Ltd.) and 'Marlex 50' (Phillips Petroleum Co.), for example, have 10–20 transvinylene groups per 10^6 carbon atoms, while other polyethylenes made by the Ziegler process may have up to 600 such groups. In view of the low-energy transfer in some corona discharges, it would seem unlikely that appreciable unsaturation could be produced in this way, although this mechanism has been suggested[3].

The absence of surface cracking or checking in fast electron-irradiated polyethylene further differentiates this type of treatment from that of corona discharges.

Radiolysis of Aqueous Solutions of Hydrogen Sulphide and an Interpretation of Radiolytic Thiol Oxidation

The radiolysis of dilute aqueous solutions of the thiols cysteine[1–3], cysteamine[4] and mercaptoethylguanidine[5,6] has been investigated by various workers, who have shown that in oxygenated systems a short chain mechanism occurs yielding the corresponding disulphide as the major product. Swallow[1] suggested the following mechanism:

$$RSH + \cdot OH \rightarrow RS\cdot + H_2O \qquad (1)$$

$$RSH + HOO\cdot \rightarrow RS\cdot + H_2O_2 \qquad (2)$$

$$RS\cdot + RSH \rightarrow RSSR + H\cdot \qquad (3)$$

$$H\cdot + O_2 \rightarrow HOO\cdot \qquad (4)$$

Littman, Carr and Brady[7] have shown that reaction 5:

$$RSH + H\cdot \rightarrow RS\cdot + H_2 \qquad (5)$$

occurs readily. Consequently, on Swallow's mechanism a chain reaction should occur in the absence of oxygen. The fact that it does not[1,2,6], and that reaction 3 is approximately 17 kcal. per mole endothermic, makes this mechanism unlikely.

To investigate further this type of reaction the radiolysis of aqueous hydrogen sulphide solutions has been examined in greater detail than previously reported[3,8].

On irradiating an oxygen-free solution of 0·0175 *M* hydrogen sulphide with cobalt-60 γ-rays product yields $G(S)$, $G(H_2)$ and $G(H_2O_2)$ of 3·4, 3·9 and 0·5 molecules per 100 eV. respectively were found. These yields agree satisfactorily with those predicted from radical and molecular product yields generally accepted for the radiolysis of dilute aqueous solutions where all radicals are scavenged[9] assuming the following mechanism:

$$H_2S + \cdot OH \rightarrow HS\cdot + H_2O \qquad (6)$$

$$H_2S + H\cdot \rightarrow HS\cdot + H_2 \qquad (7)$$

$$2\,HS\cdot \xrightarrow{H_2O} H_2S + S \qquad (8)$$

Similarly a 0·070 *M* hydrogen sulphide solution in 0·1 *N* sulphuric acid gave initial yields, $G(S)$ and $G(H_2O_2)$ of 3·4 and 0·8 respectively, again agreeing satisfactorily with predicted values for an acid solution. A slow reaction between H_2S and H_2O_2 was detected at this lower *p*H.

Table 1. Initial Yields of Sulphur from 10 ml. of a 0·0003 *M* Oxygen Solution*

$[H_2S]$ (molar)	Temperature (° C.)	Dose-rate eV. ml.$^{-1}$ min.$^{-1}$ ($\times 10^{-15}$)	$G(S)$ Molecules per 100 eV.
0·0035	ambient	8·5	8·2
0·0175	,,	8·5	13·9
0·0525	,,	8·5	16·8
0·0875	,,	8·5	18·9
0·0875	25	8·5	19·5
0·0875	0	8·5	16·6
0·0875	ambient	0·136	23·3

* Partial pressure of oxygen = 200 mm. mercury.

In the presence of oxygen the initial yield of sulphur was greatly increased, the variation of $G(S)$ with hydrogen sulphide concentration, temperature and dose rate being shown in Table 1. No hydrogen peroxide was found until the dissolved oxygen had been used, while sulphate was formed prior to oxygen depletion with an initial yield $G(SO_4^{=})$ of 6 ± 1·5 from a 0·0875 *M* hydrogen sulphide solution. These results suggest a short-chain mechanism probably involving a reaction between hydrogen sulphide molecules and reactive peroxy intermediates in the relatively slow propagation step 10:

$$HS\cdot + O_2 \rightarrow HSOO\cdot \qquad (9)$$

$$HSOO\cdot + H_2S \rightarrow HSOOH + HS\cdot \qquad (10)$$

The peroxide intermediates then probably react rapidly with themselves, with hydrogen sulphide and with hydrogen peroxide to yield finally sulphur and sulphate. Sulphur yields were the same in 1 *N* sulphuric acid solutions as in the sulphuric acid-free solutions mentioned above.

From the yields of radical and molecular products from water, and from the measured yields of sulphur and sulphate from a 0·0875 *M* hydrogen sulphide solution it follows that $G(-O_2)$ is approximately 21. It is suggested from this work that a comparable mechanism, involving the intermediate radical $RSOO\cdot$, might occur in oxygenated solutions of thiols, and that their ability to use up oxygen may partly explain their mode of protection against harmful radiation effects.

This work was carried out during the tenure of a commission in the New Zealand Defence Scientific Corps. I thank Dr. G. S. McNaughton for many useful discussions.

CHEMISTRY

Bond-Length Alternation in Heterocyclic Ring Systems

THERE has been considerable interest recently in the problem of C—C bond alternation in polyenes[1-3]. The preparation by Chapman, Paddock, Paine, Searle and Smith[4] of a series of cyclic phosphazenes $(PNF_2)_n$, where $n = 3, 4 \ldots 17$, raises the same question for heterocyclic systems $(AB)_n$ containing π-electrons. On the basis of simple molecular orbital theory, it has been shown for cyclic polyenes that, as the number of atoms in the ring N tends to infinity, the stable configuration has C—C bonds unequal in length[2]. The critical value of N for which the bonds first become unequal is uncertain; but there is evidence for bond alternation[3] in $C_{18}H_{18}$, $C_{24}H_{24}$ and $C_{30}H_{30}$.

A discussion of the problem for cyclic phosphazenes depends on the type of structure postulated[7-9]. As Craig[10] has shown, there are only two different types of bonding possible in an $(AB)_n$ ring. I shall call the type in which the orbitals on A and B have the same site symmetry, $p\pi$—$p\pi$ bonding; and the type in which they have different site symmetries, $p\pi$—$d\pi$ bonding. I use superscripts $p\pi$ and $d\pi$ to distinguish them in the argument here, which is based on the simple molecular orbital theory.

Let δ be the difference between the coulomb integrals for the orbitals on atoms A and B, and let r_1, r_2 and β_1, β_2 be the lengths and resonance integrals of alternate AB bonds. Let E be the total energy of the system, then E may be written in terms of the σ- and π-energies, E^σ and E^π respectively, as:

$$E = E^\sigma + E^\pi \qquad (1)$$

E^σ is assumed to be the sum of σ-bond energies, thus:

$$E^\sigma = n_1E_1^\sigma + n_2E_2^\sigma \qquad (2)$$

where E_1^σ, E_2^σ are the σ-bond energies of the two different A–B bonds, and n_1,n_2 the numbers of each bond. E^π cannot be written in this way.

To discuss equilibrium, we require the first and second derivatives of the energy with respect to an increase in bond-length x, evaluated at $x = 0$. I write these E_x and E_{xx} respectively. For stable equilibrium:

$$E_x = E_x^\sigma + E_x^\pi = 0 \qquad (3)$$

and

$$E_{xx} = E_{xx}^\sigma + E_{xx}^\pi \qquad (4)$$

must be positive.

For $p\pi$—$p\pi$ bonds

$$E^{p\pi} = \sum_l |[\delta^2 + 4(\beta_1^2 + \beta_2^2 + 2\beta_1\beta_2 \cos 2\pi l/n]^{\frac{1}{2}}|,$$

$$l = 0, \pm 1, \pm 2, \ldots \pm (m - 1), m$$

where $m = n/2$ for n even, and $\pm (n-1)/2$ for n odd.

For $p\pi$—$d\pi$ bonds,

$$E^{d\pi} = \sum_l |[\delta^2 + 4(\beta_1^2 + \beta_2^2 - 2\beta_1\beta_2 \cos 2\pi l/n)]^{\frac{1}{2}}| \qquad (6)$$

Now β_1 and β_2 may be written[2],

$$\beta_1 = \beta_0\, e^{ax}, \qquad \beta_2 = \beta_0\, e^{-ax} \qquad (7)$$

where $r_1 = r_0 - x$, $r_2 = r_0 + x$, a is a constant, and β_0, r_0 are the resonance integral and bond-length for equal A–B bonds.

From equations (5), (6) and (7),

$$E_x^{p\pi} = E_x^{d\pi} = 0 \qquad (8)$$

and

$$E_{xx}^\pi = \sum_l \frac{-16\,\beta^2a^2}{|[\delta^2 + 8\,\beta^2\,(1 \pm \cos 2\pi l/n)\,]^{\frac{1}{2}}|} \qquad (9)$$

with the positive sign for $p\pi$—$p\pi$ bonds and the negative sign for $p\pi$—$d\pi$ bonds. With $\delta = 0$, this reduces to the expression given by Longuet-Higgins and Salem[2].

For heterocyclic systems $\delta \neq 0$, and the denominator in equation (9) can never be zero. Thus E_{xx}^π remains finite for all values of n. E_{xx}^σ, however, tends to infinity as $n \to \infty$, as Longuet-Higgins and Salem[2] have pointed out. Thus E_{xx} must be positive as $n \to \infty$, and the equilibrium at $x = 0$ is stable. This means that, for the infinite heterocyclic ring $(AB)_n$, the stable configuration has equal A–B bonds, the opposite result to that for homocyclic rings. For heterocyclic rings there may be a critical value of n below which the bonds are unequal in length.

It would be interesting to discover if, in the cyclic phosphazenes, this critical value of n exceeds 3. To discuss this, values are needed for the parameters in equation (9), and an expression is required for E_{xx}^σ. E_{xx}^σ may be written[5]:

$$E_{xx}^\sigma = nk \qquad (10)$$

where k is the force constant for the P—N bond. I have made a rough calculation with $k = 8$ md/Å. (ref. 11), $\beta_0 = 25$ kcal./mole, and $a = 0{\cdot}4$ Å.$^{-1}$. This indicates that if δ is greater than about $\beta_0/10$, $E_{xx}^\sigma > E_{xx}^\pi$ for all values of n, and the ring with equal P—N bond-lengths is stable. If $\delta < \beta_0/10$, and n is small. E_{xx}^π might be greater than E_{xx}^σ, and a ring with unequal P—N bond-lengths would be favoured. In general, it seems probable that $\delta > \beta_0/10$, and that the P—N bonds in all cyclic phosphazenes should be equal in length.

Experimental determinations of bond-lengths and angles in cyclic phosphazenes show that the substituents have a considerable effect on the structure[12]. There is, however, no evidence for unequal bond-lengths. One of the effects of substituents is to alter δ. and the argument given above shows how a variation in δ can affect the relative importance of σ- and π-bonds in determining the structure of cyclic phosphazenes. At the present time there seems to be satisfactory agreement between theory and experiment.

I thank Mr. N. L. Paddock for sending me the typescript of a forthcoming paper.

Heat Pulses at Initiation of Liquid Explosives

The hydrodynamic theory of detonation has proved to be very fruitful for the discussion of steady detonation. According to the theory an intense shock wave is a prerequisite for the accomplishment of the chemical reaction during the short space of time that is available. The theory does not, however, explain how the shock wave is generated at initiation.

Cook *et al.*[1] assume that 'heat pulses' in some cases play an important part in the initiation process. In the present investigation the possibility of a heat pulse which propagates at a great speed without being directly associated with a shock front is discussed. It is preliminarily assumed that the temperature in a layer of nitroglycerine suddenly rises to such a height that the chemical reaction is completed by a few impacts. Owing to the relaxation of the rotational and vibrational energy the released explosion energy will be concentrated on the translational degrees of freedom[2-4] of the newly formed molecules. After some tens of collisions the molecules have approximately acquired the Maxwellian distribution of velocities and this corresponds to a 'translational temperature' T^x, which is considerably higher than the equilibrium values. The transfer of the energy to other degrees of freedom proceeds comparatively slowly. The number of collisions required for the development of rotational energy is about 10^3 and of vibrational energy about 10^5. For T^x:

$$E_e/n = 3\,RT^x/2 \qquad (1)$$

applies. E_e is the explosion energy, n the number of molecules in the detonation gas per molecule of explosive and R the gas constant. For nitroglycerine[5] $E_e = 340{,}000$ kcal./kmol., $n = 7{\cdot}25$ and $T^x = 15{,}800°$ K. The fraction of impacts which leads to decomposition is .

$$q = e^{-E_a/RT^x} \qquad (2)$$

Insertion of Roginsky's[6] value for the activating energy, $E_a = 48{,}000$ kcal./kmol , gives $q = 0{\cdot}22$. According to this $n_s = 1/q = 4{\cdot}5$ impacts are sufficient for the decomposition of the nitroglycerine molecule $C_3H_5(ONO_2)_3$, and due to the high density the reorganization of the atoms to CO_2. H_2O, N_2 and O_2 is in all probability a very rapid process. The result goes to prove that it is possible for a decomposition process of this kind to continue once it has got well away.

The mean velocity of the newly formed molecules can be obtained from the relation:

$$Mv^2/2 = E_e/n$$

in which

$$\bar{v} = 0{\cdot}92\sqrt{v^2}$$

This gives the following velocities in metres per second:

$$3\ CO_2 : \bar{v}_1 = 2{,}750;\ \ 2{\cdot}5\ H_2O : \bar{v}_2 = 4{,}300;$$
$$1{\cdot}5\ N_2 : \bar{v}_3 = 3{,}440;\ \ 0{\cdot}25\ O_2 : \bar{v}_4 = 3{,}220.$$

The figure before the gas indicates the number of molecules per nitroglycerine molecule. The arithmetical mean value for all molecules is $\bar{v} = 3{,}440$ m./s. This high molecular velocity corresponds to a high velocity for the propagation of disturbances.

For liquid nitrogen at − 199° C. the ratio between the velocity of sound and the molecular mean velocity is approximately $m = 4$, and according to Rice and Walsh's[7,8] results for water the ratio between the shock velocity and the molecular velocity lies between $m = 4{\cdot}2$ at 8 kbar. and 50° C. and $m = 5{\cdot}6$ at 250 kbar. and 1,670° C. At atmospheric pressure and room temperature the velocity of sound in water is only 2 5 times the molecular velocity, but this may be due to molecular association which makes the estimated molecular velocity too high. For organic liquids the ratio between sound and molecular velocity at atmospheric pressure and room temperature is, as a rule, between 4 and 6.

According to Campbell, Davis and Travis[9] we have the following process in transmission of detonation from a donor charge through an inert layer to a receptor charge of a liquid explosive. Behind the front of the incoming shock wave the receptor is heated by shock wave compression. If the temperature is above a certain level an accelerated rise in temperature by self heating is started. The maximum of this rise lies close to the impact surface similarly to what Selberg and Johansson[10] have shown for the environment of a wire suddenly heated. There should probably be prerequisites here for a 'heat pulse'. Campbell, Davis and Travis observed a frontal velocity of 10,400 m./s. when the particle velocity was 1,600 m./s. $\bar{v} = 3{,}440$ m./s. and $m = 5$ gives a velocity of disturbance in nitroglycerine of 17,200 m./s. In calculating the propagation velocity of the heat pulse the time for dissociation of the explosive molecules must be taken into consideration. Since a self-heating process is in progress in the receptor charge it seems reasonable to assume that $n_s < 4{\cdot}5$.

Use of Di-(2-ethylhexyl) Orthophosphoric Acid for the Separation of the Elements Lanthanum–Gadolinium by Reverse Phase Partition Chromatography

INVESTIGATIONS into the use of alkyl phosphoric acids as metal extractants have shown that there are relatively large differences between the stabilities of the complexes of individual rare earths with di-(2-ethylhexyl) orthophosphoric acid (HDEHP), the separation factor for any adjacent pair being about 2·5[1]. This figure suggests that it should be feasible to devise a comparatively simple scheme for rare earth separations based on a multi-stage extraction procedure utilizing HDEHP as extractant. If the organic reagent can be immobilized on a solid phase the effect of a number of successive extractions may be achieved by eluting the metals chromatographically from a column of the extractant, and it has already been shown that complexing agents may be incorporated into solid supports to provide column materials of this type[2-6]. Investigations into the behaviour of a number of support materials retaining HDEHP have indicated that a poly-(vinyl chloride/vinyl acetate) copolymer ('Corvic', Imperial Chemical Industries, Ltd.) will hold the complexing agent firmly and will give elution curves with the rare earths which show relatively little tailing. Using columns packed with 'Corvic' retaining HDEHP it has been found possible to separate small quantities of the elements lanthanum–cerium–praseodymium–neodymium–promethium–samarium–europium and gadolinium, using normal chromatographic techniques.

Column material was made up by mixing the poly-(vinyl chloride/vinyl acetate) copolymer with a solution of chloroform (5 ml.), toluene (3 ml.) and purified HDEHP[1] (2 ml.) in the ratio of 10 gm. of solid to 10 ml. of solution. Organic solvent was evaporated off until the total weight of 10 gm. dry weight of 'Corvic' plus the adsorbed liquid was 12·5–12·7 gm., when the resulting powder was first slurried in $N/500$ perchloric acid, then made up into a column of the required size in the usual way. The temperature of the column was thermostatically controlled at 60° C., column size was 1 cm. diameter × 30 cm. and the flow-rate was approximately 1·0 ml./cm.^{2}/min. Between 0·01 and 0·1 mgm. of the irradiated trivalent elements lanthanum-gadolinium (with the exception of promethium) were added to the top of the column, as required, in very dilute acid solution, and the column then washed with $N/500$ perchloric acid. In the initial experiments, when the behaviour of adjacent pairs of rare earths was being considered, the extracted rare earths were eluted with perchloric acid solution of constant strength, but for later experiments, when a more comprehensive separation was required, the acidity of the influent was gradually increased. For the determination of the activity in the column effluent the perchloric acid solution leaving the bottom of the column was either passed through a γ-scintillation flow counter connected to ratemeter and chart recorder, or collected in fractions of 1 ml. or less, and the activity of each fraction assayed separately. The nuclides giving rise to the measured radiation were characterized by γ-ray spectrometry or from half-life curves.

The effectiveness of HDEHP retained on 'Corvic' for the separation of the elements lanthanum–gadolinium may be gauged from Fig. 1, in which the elution of the metals, as recorded by the flow counter, is shown, together with the acidities at peak maxima.

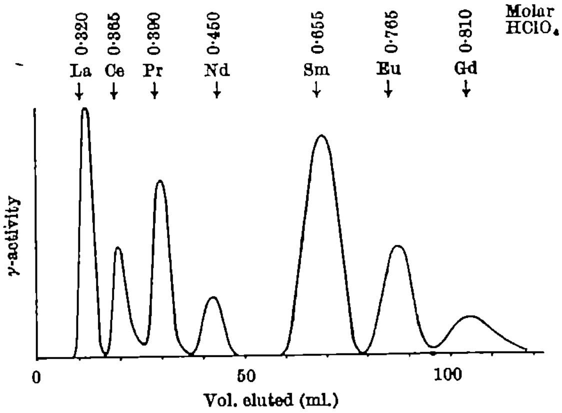

Fig. 1. Separation of the elements La–Gd by gradient elution from a 'Corvic'–HDEHP column

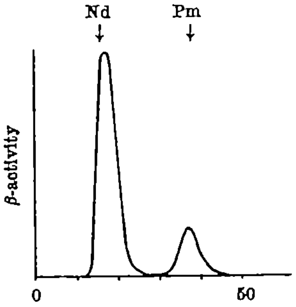

Fig. 2. The elution of Nd and Pm from a 'Corvic'–HDEHP column by 0·39 M perchloric acid

The γ-counter used was not sensitive to the largely β-active promethium, but the separation of promethium from neodymium is shown in Fig. 2. It can be seen that a good resolution of the elements is achieved by a simple gradient elution technique which relies only on the differences in the stabilities of the individual metals with HDEHP, and does not require the addition of complexing anions to the eluting phase.

The separation of cerium from praseodymium and europium from gadolinium proved troublesome when perchloric acid of constant acidity was employed as influent to the column, but gradient elution greatly reduced overlap of the elements in the effluent, and permitted a separation to be achieved, even for the europium–gadolinium pair, which has been previously shown to be difficult to isolate by different techniques[3,7].

We thank Mr. J. R. Fryer for valuable help given in the initial stages of this work.

A Simplified Method for Preparation of Very Pure Silicochloroform

A NUMBER of methods are available for the preparation of trichlorosilane ($SiHCl_3$), in the laboratory, for example, by the action of dry hydrochloric acid gas on silicon[1,2] and by the reaction of hydrochloric acid gas and metallic silicides[3-7], such as magnesium silicide, iron silicide, or 25 per cent copper silicide. Trichlorosilane has also been prepared by passing a mixture of halosilanes and excess of hydrogen or hydrogen-halide over aluminium, zinc, or magnesium[8], or by halogenation of monosilane (SiH_4), with hydrochloric acid gas in presence of aluminium chloride as a catalyst[9].

In all these methods the amount of formation of trichlorosilane is low. This is due to the fact that, along with the main reaction, which leads to the formation of trichlorosilane, side reactions also occur. These side reactions give rise to the formation of $SiCl_4$, SiH_2Cl_2, SiH_3Cl, etc. At increasing temperature the reaction leading to the formation of silicon tetrachloride occurs more rapidly[7]. The yield of silicochloroform, calculated from the weight of the reacting silicon, is about 50 per cent[4]. This low yield of silicochloroform is also due to inadequate cooling of the gaseous reaction products. The concentration of silicochloroform in the gaseous reaction products is low, and hence a very good cooling system for condensing trichlorosilane is essential. Unfortunately, liquid air cannot be used for this purpose because unreacted hydrochloric acid gas would also condense along with trichlorosilane. In methods for preparation of trichlorosilane in which silicides of metals such as magnesium, copper, or zinc are used as starting materials, instead of silicon, and hydrochloric acid gas, the process of preparing these metallic silicides is neither simple nor suitable for obtaining pure trichlorosilane. The process of preparing these metallic silicides involves first intimately mixing silicon with at least 10 per cent by weight of one of these foreign metals. After this, the mixture is usually sintered at a high temperature, normally 1,000° C., to activate the silicon. Silicon activated in this way is then subjected to the action of hydrochloric acid gas in order to produce silicochloroform. This operation of mixing silicon with another metal and then sintering at a high temperature leads to the contamination of silicon with many impurities. Therefore silicochloroform obtained by this method is not pure. To produce pure trichlorosilane it would be more practical if, instead of activating silicon, which involves contamination of silicon with impurities, the other reagent, hydrochloric acid gas, could be activated by some process.

Considering the drawbacks of these available methods, we have been able to develop an improved simple method, which can be used on a laboratory or production scale for the preparation of pure trichlorosilane. The over-all reaction is:

$$Si + 3HCl \longrightarrow SiHCl_3 + H_2$$

In this method for the preparation of pure trichlorosilane, instead of activating silicon, which is normally accomplished by mixing it with some other metal such as magnesium, copper, or iron, and sintering the mixture at a high temperature, which results in the contamination of silicon with impurities, hydrochloric gas molecules are activated. The activation of hydrochloric acid gas molecules takes place, possibly due to the presence of $HCuCl_2$-type complexes. These $HCuCl_2$-type complexes are formed because of the presence of very small amounts of cuprous chloride, etc., in the reaction tube. The quantity of copper therefore required is very small, being less than 0·1 per cent of the weight of silicon in the reaction tube. These activated hydrochloric acid molecules react with silicon to produce pure trichlorosilane, while the impurities which are present in silicon are left behind. The gaseous reaction products from the reaction tube when condensed in our specially developed condenser, as in Fig. 1, give an average silicochloroform yield of about 90 per cent, calculated from the amount of reacted silicon.

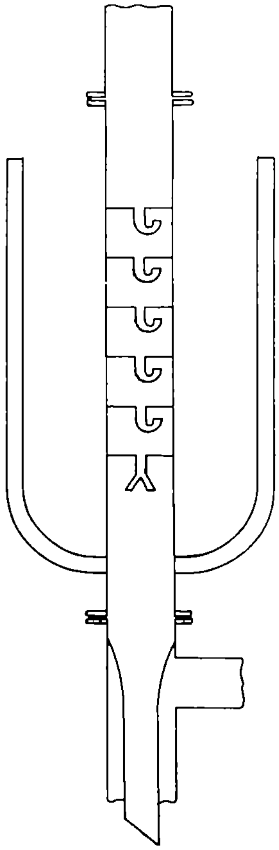

Fig. 1

The apparatus used in its simplest form consists of a horizontal 'Pyrex' tube. A weighed quantity of small crystals of silicon, 1–5 mm. in size, is placed in a quartz boat. This boat containing silicon is introduced into the reaction tube, which is 500 mm. long and has an inner diameter of 25 mm. The inner wall of the middle part of the reaction tube, where the boat containing the silicon lies, is fitted with a copper spiral. This copper spiral weighs approximately 0·1 per cent of the weight of silicon in the boat. The copper spiral is so arranged that it cannot possibly come in contact with the silicon and lies quite apart from it. A chromium–nickel resistance wire is wound around the middle portion of the reaction tube to heat it to the required reaction temperature in conjunction with an ordinary 10-amp. and 0–250 V. 'Variac'. At one end of the reaction tube is an inlet for the incoming gases while its other end is joined to a specially developed condenser (Fig. 1) for condensing silicochloroform vapours. This condenser in turn is connected to a collecting flask. for collecting trichlorosilane, which has an outlet allowing the uncondensed gases to escape into the atmosphere. A thermo-couple, nickel/nickel–chromium, is placed in such a way that it lies just on the surface of the silicon for measuring the reaction temperature. After arranging the apparatus, a current of hydrogen is passed through it to drive out all the air. The reaction tube is next heated to the reaction temperature of 400° C. by passing a current through the resistance wound around it. At the same time, the condenser is cooled by means of alcohol and dry ice (– 78° C.). Next hydrochloric acid gas is led into the reaction tube at the rate of 105 litres per hour, while the flow of hydrogen is stopped. The reaction starts, the pure silicochloroform forming in the condenser and collecting in the storing flask. The relationship between the rate of overall reaction, $Si + 3HCl \longrightarrow SiHCl_3 + H_2$, and the reaction temperature and the rate of flow of hydrochloric acid gas was investigated. The results obtained from these investigations are given in Tables 1 and 2.

Table 1. RELATIONSHIP BETWEEN THE RATE OF REACTION AND THE REACTION TEMPERATURE

Reaction temperature (° C)	Hydrogen chloride rate of flow (l./hr.)	Weight of silicon reacting (gm./hr.) In absence of copper spiral	Weight of silicon reacting (gm./hr.) In presence of copper spiral
300	105	0 80	2 1
350	105	2 3	5·1
400	105	3 1	8 0

Table 2. RELATIONSHIP BETWEEN THE RATE OF REACTION AND THE RATE OF FLOW OF THE HYDROCHLORIC ACID GAS

(The investigation was carried out only in presence of a copper spiral)

Hydrochloric acid gas rate of flow (l./hr.)	Reaction temperature (° C)	Weight of silicon reacting (gm./hr.)
43	400	5 9
72	400	8 0
105	400	8 0

From trichlorosilane, obtained by this method, silicon was produced. The results of the spectroscopic analysis of this silicon and that used as the starting material for the preparation of trichlorosilane are given in Table 3.

Table 3. COMPARISON OF THE SPECTROSCOPIC ANALYSIS OF RAW AND PURE SILICON

Elements present as impurities	Raw silicon concentration (per cent)	Pure silicon concentration (per cent)
B	0·002	—
Fe	0 0005	—
Mg	0 0002	—
Al	0 002	—
Cu	0·0002	—
Ti	0 0005	—

BIOCHEMISTRY

Calculated Composition of a 'Messenger' Ribonucleic Acid

A SPECIAL type of ribonucleic acid, the 'messenger' RNA, has been postulated recently, which is assumed to specify the sequence of the amino-acid constituents of a given protein[1]. This RNA is said to be made under the control of deoxyribonucleic acid and to mirror the composition and the regularities (base-pairing, etc.)[2] of the latter, with uracil substituting for thymine[3–6]. The existence, in DNA, of a non-overlapping, 'degenerate' code, composed of nucleotide triplets that are 'read' from a fixed starting point, has also been put forward[7]. These advances have been paralleled by the equally recent elaboration of what would seem to be the complete amino-acid code in the form of a series of nucleotide triplets[8–11].

If all this be accepted, a way towards the indirect establishment of the nucleotide sequence of 'messenger' RNA would seem to be open. The composition of many proteins is known precisely, and in several instances also the specific sequence of the amino-acids. The determination of the nucleotide arrangement in RNA, on the other hand, is beset with great difficulties.

I have attempted to reconstruct the composition of the supposititious 'messenger' RNA that would code for bovine pancreatic ribonuclease, in order to see whether a plausible structure would emerge. The results are peculiar. The computation is based on the well-established composition of this protein[12] and on the triplet 'letters' proposed in recent papers. Thirteen of the required nineteen coding units were taken from Speyer *et al.*[10]; those for glutamic acid and alanine came from Martin *et al.*[11]; with regard to four components, aspartic acid (UAG), methionine (UAG), asparagine (UAA) and glutamine (UCG), only information published in the daily Press was available[13].

The following approximate composition of the 'coding' RNA results: $A_{63}\,G_{59}\,C_{77}\,U_{173}$; or, as mole per cent. A, 16·9; G, 15·9; C, 20·7; U, 46·5. (A, G, C, U, stand, respectively, for adenylic, guanylic, cytidylic and uridylic acids.)

A ribonucleic acid of this composition must create some surprise. If it exists, it has not been seen. The strikingly high content in uridylic acid, nearly a half of the hypothetical molecule, is in contrast to almost all available information[14]. Also other features of the constructed molecule are most unusual: the ratio of A to U is 0·36; the purines account for only one-third of the nucleotides; the ratio of 6-amino to 6-keto nucleotides[15] is 0·60. Moreover, the inspection of the proposed code. with its baffling richness in uridylic acid, makes it unlikely that many proteins would be found to demand less implausible 'messengers'. If the assignment of coding units really proved to be correct, auxiliary hypotheses would be required, in order to explain the discrepancy between the composition of the 'coding' RNA under discussion and that of 'messenger' RNA exhibiting the regularities of DNA. The most obvious, but still unwarranted, assumption may surmize the production of the 'messenger' in the form of two polynucleotides, complementary with respect to base-pairing, of which only one determines the protein; a postulate that leaves the function and the fate of the other half very much in doubt. Here, I wish to limit myself, however, to pointing out certain perplexing elements.

In vivo and *in vitro* Incorporation of Amino-Acids by Melano-Protein Particles of the Harding–Passy Mouse Melanoma

ELECTRON microscopic evidence indicates that the formation of melanin granules in melanocytes occurs in a region of the cell associated with the Golgi membranes[1,2]. Although the characteristic flattened sacs and vesicles of this structure are evident in many types of vertebrate and invertebrate cells, the vesicular profiles are particularly apparent in cells concerned with secretion and absorption[3], and differ in several morphological respects from the endoplasmic reticulum[4]. The biochemical composition and role of this membrane structure in the formation of melanin granules are not yet established.

This communication reports a procedure for the isolation of a particle fraction rich in melano-protein and lipid, and a comparison with other cell particulate fractions of the capacity of the melano-protein particles to incorporate amino-acids *in vivo* and *in vitro*.

Harding–Passey melanoma tissue was homogenized with a loose-fitting Potter–Elvehjem glass homogenizer in 2·3 vol. of a medium containing 0·15 *M* sucrose, 0·01 *M* magnesium chloride, 0·025 *M* potassium chloride and 0·035 *M tris* buffer, *p*H 7·8. The melano-protein particle fraction and the mitochondria were isolated by an initial low-speed centrifugation at 600*g* for 5 min. to sediment nuclei and broken cells, followed by a higher speed centrifugation at 10,000*g* to collect mitochondria and melano-protein particles. (All centrifuged forces are calculated from the bottom of the tube.) Tumour microsomes were obtained after centrifugation for 1 hr. at 144,700*g* in a 'Spinco' preparative centrifuge. The pellet obtained at 10,000*g* was suspended in homogenizing medium and placed as the top gradient in a 5-ml. centrifuge tube layered in advance with 1·0 ml. 1·7 *M* sucrose and 1·0 ml. 1·5 *M* sucrose. The tubes were centrifuged in a swinging bucket rotor *SW L* of the 'Spinco' centrifuge for 1 hr. at 173,000*g*. Under these conditions melano-protein particles separate from lighter tumour mitochondria and are collected as a pellet at the bottom of the tube together with some heavier tumour mitochondria. Other less-dense melanin-rich particles can be observed, and these appear to be related to the age and degree of melanization of the tumour. The melanin-rich proteins are referred to as melano-protein particles in Table 1 and constitute 6–9 per cent of the total protein of the tumour.

Table 1. INCORPORATION OF ALGAL PROTEIN HYDROLYSATE *in vivo* INTO CELL FRACTIONS OF THE HARDING–PASSEY MOUSE MELANOMA. CONDITIONS DESCRIBED IN TEXT

Cell fraction	Time (hr.)	C.p.m./cm.^{2} (protein)	C.p.m./cm.^{2} (NA)	Percentage total (protein)	Percentage total c.p.m. (protein)	Mgm. RNA/mgm. protein
Nuclei cells broken cells	0·5	336	48	22·1	19·2	0·002

NA, Nucleic acid. C.p.m are expressed at infinite thickness

Table 1 shows the distribution of labelled amino-acids in protein and nucleic acid of the isolated tumour cell fractions, and the protein and RNA content of each cell fraction following an intraperitoneal injection of 0·5 µc. algal protein hydrolysate per gm. of mouse tissue. 100 µmol. of non-labelled carrier tyrosine was injected at the same time as the hydrolysate to dilute radioactive tyrosine present in the hydrolysate. The activity of the proteins recorded in Table 1 is therefore indicative of the rate of synthesis of the protein component of the melano-protein particles. After 0·5 and 3·0 hr. following injection, the melano-protein fraction accounts for 0·7 and 9·8 per cent of the total activity incorporated by the tumour *in vivo*.

Fig. 1 illustrates the time-dependent incorporation of L-valine-^{14}C *in vitro* into protein of three cell fractions obtained at 600*g*, 10,000*g* and 173,000*g*. The complete reaction mixture consisted of 0·5 µc. L-valine-^{14}C (1·54 µmol./µc.), 3·0 mgm. of the particulate tumour protein, 5·0 µmol. magnesium chloride, 10 µmol. potassium phosphate, 10 µmol. glucose, 75 µmol. sucrose, 12·5 µmol. potassium

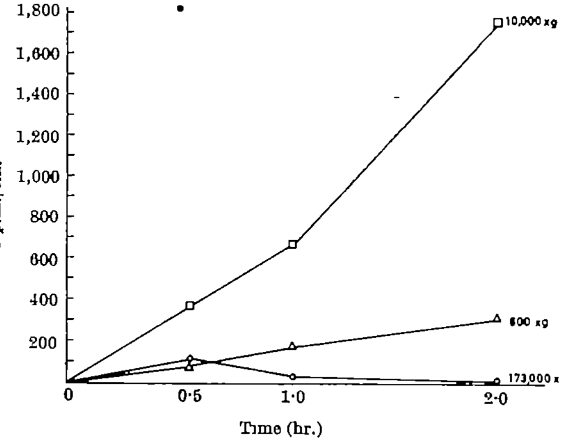

Fig. 1. Incorporation of L-valine-^{14}C *in vitro* into cell fractions of the Harding–Passey mouse melanoma. Conditions described in text. C.p m are expressed at infinite thickness

chloride, 0·1 μmole diphosphopyridine nucleotide, 1·0 μmole adenosine triphosphate, 10 μmol. carbamyl phosphate, 15 μl. carbamyl phosphokinase (0·61 μmol. ATP/min./μl.) and 20 μmol. *tris* buffer, *p*H 7·8 in a final volume of 1·0 ml. Under these conditions the particles obtained at 10,000*g* have the highest specific activity and continue to incorporate L-valine at an increasing rate for 2 hr. Further purification of this pellet by sucrose gradient centrifugation shows that essentially all the radioactivity sediments with the melanin-rich particles. Tumour microsomes reach a maximum rate of incorporation at or before 0·5 hr., and show a decreasing rate of incorporation after this time-interval. The activity of the melano-protein particles is not dependent upon an external supply of ATP. The omission of ATP, carbamyl phosphate and carbamyl phosphokinase does not reduce the incorporation, nor does the addition of ribonuclease inhibit the reaction. In a subsequent communication the evidence that suggests that the particles meet the energy requirement for the incorporation from ATP synthesized during anaerobic glycolysis will be presented. In addition to a high content of melanin, the particles contain 35 per cent lipid of which 5 per cent is phospholipid. Electron micrographs of the isolated particle fraction reveal vesicles with enclosed melanin granules in various stages of synthesis. There are no characteristic ribonucleoprotein particles visible, although RNA is present in the particles (Table 1). The radioactive proteins of the particles show solubility characteristics expected of that of melano-protein.

This work represents an attempt to extend to the biochemical level the reactions involved in melano-protein synthesis, and agree with the electron microscopic evidence obtained by others[1,2] that biologically active membrane structures exist in melanocytes which differ biochemically and morphologically from tumour microsomes and which may participate directly in the biosynthesis of specialized cell proteins.

This work was supported in part by a grant from the U.S. Public Health Service and the Swedish Cancer Society.

Rapid Procedure for Monitoring Steroid Transformations

THE Δ^1 dehydrogenation of 12α-fluoro,11β-hydroxytestosterone by *C. simplex* is an extremely fast reaction. Peak conversion to product may occur within 1 hr. after addition of the substrate. Furthermore, the product is quickly degraded after the reaction is completed. A reaction of this type requires a rapid method of determining harvest time.

Several paper chromatographic solvent systems using descending solvent-flow were examined at 22° C. Bush-type systems[1], such as benzene–ethanol–water, were unsatisfactory because of the time required for development of the chromatogram plus the resulting poor separation. A Zaffaroni-type system[2], toluene–propylene glycol, gave good resolution but was unsatisfactory as a monitoring system since a 15-hr. solvent development was required.

The combination of a horizontal solvent-flow and an elevated temperature has been used successfully to achieve a rapid separation (1–4 hr.) of carbohydrates[3], volatile fatty acids[4], and amino-acids[5-7] that normally require 16–40 hr. by the classical room temperature descending techniques.

Based on the ability of horizontal paper chromatography at an elevated temperature to achieve such rapid separations, the technique was applied to the present problem with rewarding success. A horizontal solvent development at 60° C. using toluene–propylene glycol separates 1-dehydro,12α-fluoro,11β-hydroxytestosterone from 12α-fluoro,11β-hydroxytestosterone in 60 min.

The developing solvent is prepared at 22° C. in a temperature-controlled room by equilibrating equal volumes of toluene and propylene glycol. The propylene glycol-rich lower layer is discarded. The toluene-rich upper phase is placed in the trough of a stainless steel chromatographic chamber, measuring 10½ in. square and 2 in. deep. The design of the chamber is identical to that previously reported[3], except that the size has been increased. The bottom of the chamber is covered with toluene in order to maintain a toluene atmosphere within the chamber. The glass-covered chamber is housed in a mechanical convection oven at a temperature of 60° C.

Ethanol-washed Whatman No. 1 filter paper, 17 cm. × 22 cm., is used. The origin is 4·5 cm. from one end. A 2·5-cm. tab, folded at a right angle to the paper, is inserted into the solvent trough. The opposite end of the paper is serrated using pinking shears and a 1·0-cm. tab is folded at right angles to the paper to permit the easy flow of solvent off the paper strip. The manner in which the filter paper strip is supported in a horizontal position has been described previously[3].

After spotting, the paper is impregnated with propylene glycol by dipping it into a 10 per cent solution of propylene glycol in chloroform. The origin end of the paper is dipped first, just up to the origin, and blotted. The remainder of the strip is then passed through the dipping solution with a rapid pass over the origin.

Following the dipping step, the strip is hung in a hood until the odour of chloroform can no longer be detected. The strip is then placed in the chamber and treated with the developing solvent for 60 min. at 60° C.

After development with the solvent, the strip is dried for 10 min. at 90° C. The positions of the steroids are located by examining the chromatogram with a zinc silicate coated paddle over an ultra-violet light source[8]. The following $R_{\text{substrate}}$ values were obtained: 1-dehydro,12α-fluoro,11β-hydroxytestosterone 0·4; 12α-fluoro,11β-hydroxytestosterone 1·0; and 1-dehydro,12α-fluoro,11β-hydroxyandrostenedione 1·8.

The Δ^1 dehydrogenation of 12α-fluoro,11β-hydroxytestosterone by *Corynebacterium simplex*[9] was conducted in a 100-gal. stainless steel fermentor. The medium contained 0·10 per cent 'Yeastamin', 0·11 per cent 'Cerelose', 0·10 per cent monopotassium phosphate, and tap water to volume. The *p*H of the medium was adjusted to 7·5 with sodium hydroxide before sterilization. The fermentation was conducted

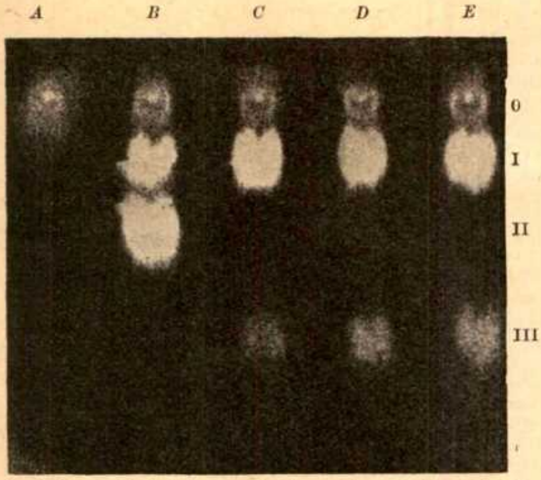

Fig. 1. Ultra-violet photocopy of a chromatogram after a 60-min. solvent development at 60° C. in the solvent system toluene–propylene glycol: *A*, broth sample before steroid addition; *B*, 15 min. after substrate addition; *C*, plus 1 hr.; *D*, plus 2 hr.; *E*, plus 3 hr.; O, ultra-violet-absorbing impurities at the origin, I, 1-dehydro,12α-fluoro,11β-hydroxytestosterone; II, 12α-fluoro, 11β-hydroxytestosterone; III, 1-dehydro,12α-fluoro,11β-hydroxy-androstenedione

at 25° C., using an aeration equal to a superficial air velocity of 1·0 ft./min. at 10 lb./sq. in. and agitation equal to 0·2 horse-power/100 gal. of broth. The sterilized medium was inoculated with 5 per cent by volume of suitable germinator inoculum propagated in the usual manner. The steroid substrate (100 μgm./ml.) was added after 24 hr. of growth as a sterile solution in methanol.

The conversion of the substrate to the product was monitored at intervals of 1 hr. 8-ml. aliquots of whole broth were extracted in cork-stoppered test tubes with 1·5 ml. of methyl isobutyl ketone by shaking for 5 min. on a reciprocating shaker operated at 360 two-in. strokes per min. The contents of the tubes were centrifuged at 2,000 revs. per min. for 5 min. after which the steroid-rich methyl isobutyl ketone layers were spotted and chromatographed.

A composite chromatogram, Fig. 1, of the individual hourly samples shows that the conversion of 12α-fluoro,11β-hydroxytestosterone to 1-dehydro,12α-fluoro,11β-hydroxytestosterone was completed within 1 hr. after substrate was added. Prolonging the reaction past the point of peak conversion results in the increase in concentration of a secondary product, 1 - dehydro,12α - fluoro,11β - hydroxyandrostenedione (Fig. 1, III). This secondary product appears in the 1-hr. sample and slowly increases in concentration with time.

Photometric Method for Estimating Amylase

METHODS for estimation of amylase are legion. H. Wildner[1] has cited some 150 methods. Furthermore, it seems that many workers apply their own modifications. Generally speaking, the majority of methods used are based on one of the following principles: (1) measurement of the decrease in the viscosity of the fluids during the enzymatic hydrolysis of starch; (2) measurement of the increase in reducing sugars; (3) observation of the change in the colour reaction with iodine going from strictly blue through violet and red to pale yellow or colourless. The colour-reaction method would be a very simple and suitable one, were it not complicated by the fact that the colour changes in a double manner, qualitatively (blue-violet-red, etc.) and quantitatively (decrease in colour intensity) at the same time.

In applying the colour reaction, different methods for obtaining an estimate have been suggested ranging from visual observation of the colour[2–4] to comparison with some suitable colour standard[5–7] and various colorimetric readings[8–10]. During a work on fungal and bacterial amylases it was observed, in this laboratory, that photometric measurement in monochromatic light, for example, at a wave-length near the maximum absorption of the initial pure blue colour, is not suitable, owing to a rather abrupt decrease in the absorption at that particular wave-length. On the other hand, if the colour reactions given by a series of samples drawn from an enzyme reaction mixture at definite time-intervals are read in polychromatic light in a photometer supplied with a neutral grey filter, it turns out that the light absorption, when plotted in an extinction-time diagram, falls off in a way closely resembling a logarithmic-type curve. Accordingly, when $\log E$ is plotted against time, a perfectly straight line is, indeed, obtained.

A procedure for determining amylase activity, based on this straight-line correlation, has been used in this laboratory with good results.

To 3 ml. of a 1 per cent solution of starch (soluble starch, Merck) in 0·1 *M* Sörensen phosphate buffer *p*H 6·9 containing 0·01 *M* sodium chloride is added a suitable sample of the enzyme solution to be tested, and the volume made to 6 ml. with distilled water. The mixture is placed in a water bath at 39° C., and the degradation of the starch is followed thus: at certain time-intervals, depending on the enzymatic activity, but easily learnt by experience, 0·50 ml. samples are transferred into test tubes containing 2 ml. 0·2 *N* sulphuric acid followed by addition of 0·2 ml. of a 0·015 *N* iodine solution. When the colour, successively, has shifted to suitable degrees, which are, likewise, observed by experience, 4–5 samples, 0·50 ml. each, are taken from the reaction mixture and transferred to test tubes containing 5 ml. 0·2 *N* sulphuric acid. The appropriate times for the withdrawal of these samples are exactly noticed and the test tubes placed in an ice bath for addition of iodine and photometric reading later on.

When the last sample has been taken, measurements are made as follows (the procedure may be interrupted at this point for some hours, if the temperature is kept low):

The acidified samples are allowed to rise to room temperature, and 0·20 ml. 0·015 *N* iodine solution is added. The colour fades somewhat with time, and the photometric reading is, therefore, made

Table 1. ESTIMATION OF AMYLASE ACTIVITY (A)

† A fairly good agreement is observed between the proportion $A_{\rm I} : A_{\rm II} : A_{\rm III} = 1 : 1{\cdot}98 : 3{\cdot}03$, as obtained by experiment, and the theoretical value 1 : 2 : 3.

exactly 2 min. after the addition of iodine. For reference, a blank is made identical with the samples, except that no starch is present. A Zeiss model Elko II spectrophotometer, supplied with a neutral grey filter of a suitable optical density, has been successfully used.

Results from a typical experiment are recorded in Fig. 1 and Table 1.

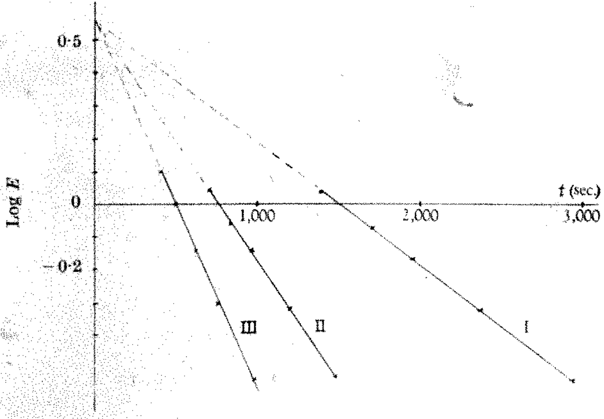

Fig. 1

It is seen that the points follow straight lines. The lines are, further, converging toward the same point on the y-axis, indicating the light absorption at zero time. The slopes of the lines are directly proportional to the amounts of enzyme. Accordingly, the time-interval corresponding to any definite light absorption is inversely proportional to the enzyme activity. Within the limits of minor experimental errors the experimental values are in good agreement with the theoretical ones.

For convenience, we have in our laboratory established the following expression for amylase activity as measured under the above conditions: amylase activity $= A = 10^4 \times t_{0 \cdot 8}^{-1}$, where $t_{0 \cdot 8}$ is the time, expressed in seconds, corresponding to $\log E = -0{\cdot}2$ or $1 + \log E = 0{\cdot}8$ or $E = 0{\cdot}6310$.

A simplification in calculating the activity is achieved as follows: strictly speaking, one needs only two photometric measurements for calculation of $t_{0 \cdot 8}$ by interpolation. If $E_1 > 0{\cdot}6310 > E_2$, one gets:

$$t_{0 \cdot 8} = t_1 + \frac{1 + \log E_1 - 0{\cdot}8}{\log E_1 - \log E_2} \times (t_2 - t_1)$$

Quite another question is: Why are log E, E being in itself a logarithmic function, and the time interconnected by a linear function of that sort? I can offer no explanation for this. Whatever it may be, the principle has proved useful as a basis for a reliable and simple estimation of amylase.

Development Techniques for the Separation of Amino-acids on DEAE Cellulose Paper

THE term 'development' is used here to describe the process of chromatographic separation. Anion exchangers based on a cellulose matrix have been found to be fundamentally more useful for the separation of amino-acids than anion exchangers based on a resin matrix of the polystyrene type[1,2].

Additional utility is conferred on any medium when it is available in the form of a paper. Techniques have been developed which are peculiar to the paper form of an ion-exchange material and which increase the scope of ion-exchange chromatography. One such technique, in which ion-exchange and conventional type separations are combined on a two-dimensional chromatogram, has already been described[3-5].

The present communication is concerned with the use of DEAE cellulose paper in conjunction with techniques of development which further emphasize the convenience and flexibility of the ion-exchange paper and which are concerned mainly with the ability of a paper to offer a preformed bed of dry ion-exchange material with very high mechanical stability.

A wet-start development technique. The usual procedure in column techniques is to equilibrate the column with the developing solvent prior to the application of the mixture under test. This technique has been simulated on the paper form of DEAE cellulose in the chromatogram illustrated in Fig. 1. Equilibration with 0·001 M sodium chloride was carried out by means of a descending chromatographic wash for 24 hr. The paper was then carefully and evenly blotted to remove as much of the capillary liquid as possible and the amino-acids were applied in slightly alkaline solution (pH 8) to the damp paper and the chromatogram developed with 0·001 M sodium chloride solution for 3 hr. The solvent front was not, of course, visible during development. The separated amino-acids were revealed on this and all other chromatograms by spraying with a 0·2 per cent solution of ninhydrin in acetone containing 10 per cent acetic acid.

Dry-start development techniques. The technique of dry-start development which has been described in

connexion with strong cation exchange papers[6] cannot be practised on the weak exchangers because of hydrolysis which occurs as the equilibrating electrolyte is removed by a water wash. Because of this, dry-start techniques used on DEAE cellulose paper are generally characterized by a *p*H gradient from solvent front to solvent source. In this technique, which is peculiar to paper media, the amino-acids were applied to the dry, untreated, free base form of the paper. Fig. 2 illustrates a chromatogram developed in this manner with 0·001 *M* sodium chloride. The resolution obtained is higher than that shown in Fig. 1, where the same solvent was used in conjunction with the wet-start technique.

The effect of the induced *p*H gradient in such a system is added to by the gradient in capillary liquid distribution from solvent front to solvent source, which assists resolution and which characterizes paper chromatograms irrigated in an initially dry state[7].

The chromatogram illustrated in Fig. 3 is a further example of a dry-start development technique using a *p*H gradient. The DEAE-cellulose paper was again used in its dry, free-base form and the developing solvent was a 0·01 *M* *p*H 4·5 buffer. The gradient operating in this chromatogram covered a lower region of the *p*H scale and an improved resolution was obtained among the slower-moving amino-acids relative to that shown in Fig. 2.

When these results are considered in the light of the fact that the particular DEAE-cellulose used for these experiments was an uncross-linked, relatively low capacity (1 mequiv./dry gm.) exchanger, they promise considerable future potential for this type of anion exchanger as a high-resolving chromatographic medium.

Structure of Lathyrine

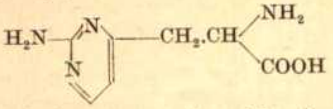
In a preliminary report[1] the isolation of a new amino-acid, giving a red colour with ninhydrin, from seeds of *Lathyrus tingitanus* was described. The molecular formula was given as $C_7H_{10}O_2N_4$ and the apparent pK_a values of its one carboxyl and two proton accepting groups as 2·4, 4·1 and 9·0. The compound showed an absorption maximum, varying with *p*H between 285 and 300 mμ, which disappeared when an aqueous solution of the amino-acid sulphate was hydrogenated over Adam's catalyst. The reduced compound contained a guanidino or substituted guanidino group and gave a purple colour with ninhydrin.

It is now reported that lathyrine absorbs two molecules of hydrogen when reduced under these conditions, and that the reduced compound has been isolated as a monohydrate m.p. above 250° (decomp.) $[\alpha]_D^{22°}$ + 64·11 in water (c., 1·1). Found: C, 40·87; H, 7·91. $C_7H_{14}O_2N_4.H_2O$ requires C, 41·18; H, 7·84 per cent.

This finding suggests that the guanidino group detectable in the reduced compound is part of a reduced ring and that lathyrine itself is a substituted 2-amino-pyrimidine. The second pK_a value of lathyrine and its absorption maximum correspond closely to the values of 2-amino-4-methyl-pyrimidine (pK_a 4·15 (ref. 2) or 4·25 (ref. 3); $\lambda_{max.}$ 289–299 mμ varying with *p*H (ref. 3)).

Both lathyrine and the reduced compound reacted as α-amino mono-carboxylic acids when treated successively with cupric nitrate and ninhydrin[4], indicating that the three remaining carbon atoms are arranged together as an alanyl group or separately as glycyl and methyl groups.

The nuclear magnetic resonance spectrum at 56·4 Mc./sec. for a solution of lathyrine in deuterium oxide showed four bands (in p.p.m. from internal *tert.*-butanol); a doublet (1·97) and a triplet (2·88) each having some fine structure and two equally split (5 c./sec.) doublets (5·46 and 6·96 respectively). The multiplicity of the high-field doublet–triplet pattern was characteristic of a $.CH_2.CH:$ grouping confirming the presence of an alanyl side-chain. The positions, separation and splitting of the two low field doublets indicate the presence of vicinal protons in an amino-pyrimidine nucleus[5] according with the presence of a single (alanyl) group in the 4 position and β-(2-amino-pyrimidine-4-yl) alanine as the structure of lathyrine.



This conclusion was confirmed by the study of the nuclear magnetic resonance spectrum of 2-amino-4-methyl-pyrimidine in deuterium oxide solution. This spectrum showed a singlet (1·02) due to the methyl group and two doublets (5·34 and 6·81) with a splitting of 5 c./sec.

It may be noted that the fine structure of the high field doublet and triplet in the spectrum of lathyrine disappeared when the spectrum was measured in acid solution but developed into a twelve-line *ABX* pattern[6] in alkaline solution.

We thank Profs. W. Robson and H. Harris for their interest in this work, Dr. J. Walker for a gift of 2-amino-4-methyl-pyrimidine, and Mr. J. I. H. Rees, of the University of London Botanic Supply Unit, for growing the seed.

PHYSIOLOGY

Relative Effects of a Deficiency in Calcium or Phosphorus and Vitamin D on the Clinical Appearance and Composition of the Skeleton and the Teeth of the Sheep

ALTHOUGH it is generally agreed that the teeth are less sensitive than the skeleton to the effects of dietary deficiencies of calcium, phosphorus or vitamin D (ref. 1), observations made during a recent investigation of sheep suggest that much depends on the criteria by which the effects of the deficiencies are judged. The present work also provides evidence on the relationship between tooth quality and the carbonate to phosphate ratio of the mineral phase, discussed by Sobel[2].

Three groups of Blackface sheep were fed from 6 to 18 months of age on diets deficient in phosphorus and vitamin D (group *C*), or in calcium (group *B*), or on a diet containing adequate quantities of all three nutrients (group *A*). At the end of the treatment period, 6 animals from each group were killed, and the remaining 7–9 animals in each group were fed on diets adequate in these constituents for a further 12 months.

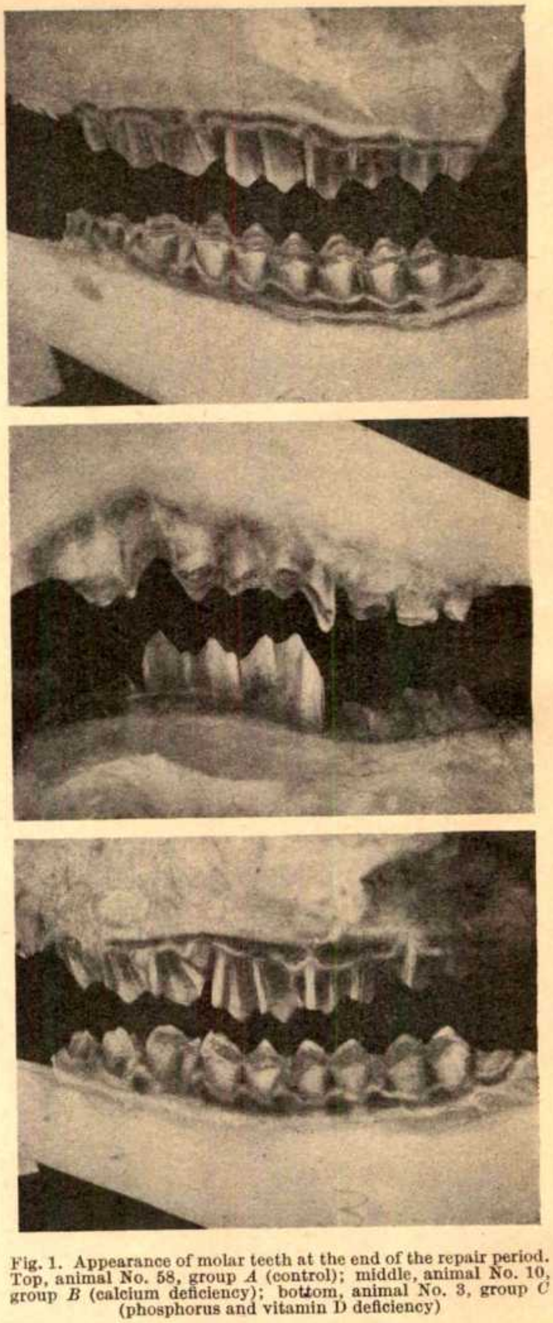

Fig. 1. Appearance of molar teeth at the end of the repair period. Top, animal No. 58, group *A* (control); middle, animal No. 10, group *B* (calcium deficiency); bottom, animal No. 3, group *C* (phosphorus and vitamin D deficiency)

After 12 months on the deficient diet, the sheep in group *C* had leg deformities that were compatible with rickets. In group *B* no rachitic signs were observed in radiographs of the radii (Table 1). Thus, clinically, the skeletons of group *C* animals were defective while those of group *B* animals were not. In contrast, marked clinical abnormalities were observed in the teeth of most of group *B* animals, but practically none was observed in those of groups *A* and *C*. During the 12-month period on deficient diets and during the subsequent 12-month repair period, the eruption of permanent incisors was markedly delayed in group *B* animals compared with those of group *A*, while in group *C* the permanent incisors erupted slightly earlier than those of group *A*. Furthermore, abnormal wear, primarily of the permanent incisors, third molars and third permanent premolars, had occurred in most animals of group *B* (Fig. 1*B*) when they were killed at 30 months of age, while comparable changes were not observed in animals of groups *A* and *C* (Figs. 1*A* and *C*). From these clinical observations of the skeleton and the teeth, the diet deficient in calcium had a greater effect on the teeth than on the skeleton, while the diet deficient in phosphorus and vitamin D had a greater effect on the skeleton than on the teeth. A somewhat similar conclusion was reached by Gaunt and Irving[3] from earlier work at this Institute in which histological and chemical observations were made on the teeth of rats.

The generalization stated in the first paragraph of this communication regarding the relative effects of mineral deficiencies on the skeleton and the teeth was derived largely from ash analyses of teeth and bone, and similar results from the present experiment (Table 1) would also support this view.

Table 1. RADIOLOGICAL VALUES AND CHEMICAL COMPOSITION OF BONES AND TEETH OF GROWING SHEEP AT THE END OF A TWELVE-MONTH PERIOD ON DEFICIENT DIETS

	Group		
	A	*B*	*C*

CO_3/PO_4 (whole tooth)	0·078	0·085	0·106

* Method described by Benzie, Boyne, Dalgarno, Duckworth, Hill and Walker (ref. 4).

Sobel[2] discussed evidence indicating greater solubility of apatite with a high carbonate to phosphate ratio than when the ratio is low, and linked a high ratio with poor quality of the tooth with respect to caries. There are numerous ways of judging quality, but in the present experiment with sheep the teeth of highest carbonate to phosphate ratio were those of animals deficient in phosphorus and vitamin D (Group *C*) (Table 1), and as judged by clinical observations of wear, their teeth were of good quality, while those of animals deficient in calcium (group *B*) that had a lower carbonate to phosphate ratio were of poor quality. The ratio for teeth of animals on an adequate diet (control group *A*) was very similar to that for group *B*; and so no evidence of a relationship between carbonate to phosphate ratio and tooth quality was found.

This investigation was carried out during the tenure of a predoctoral fellowship from the National Institute of Dental Research, U.S. Public Health Service.

Antigen-dependent Stimulation of Synthesis of Deoxyribonucleic Acid in Spleen Cells from Immunized Rabbits

PREVIOUS work[1] has indicated the importance of cell division for antibody production in an *in vitro* spleen cell system. These findings prompted an investigation of the factors affecting the synthesis of deoxyribonucleic acid (DNA) in these preparations. The experiments described here demonstrate that the addition of antigen to the incubation medium stimulates the synthesis of DNA in spleen cells from previously immunized rabbits. The stimulation is antigen-specific.

The rabbits were immunized by a month course of intravenous injections of alum-precipitated antigen. One or more months after the last injection the spleen was removed and a cell suspension prepared as previously described[2]. Samples of the suspension containing 1 × 10^7 cells were incubated with 0·2 μc. of thymidine labelled with carbon-14 (at 18·3 mc./m.mole) in a total volume of 1·7 ml. of a modified Eagle's medium. At the end of incubation the cells were washed twice in 0·85 per cent saline and dissolved in 0·4 *N* sodium hydroxide. The DNA was precipitated by the addition of salmine as described by McIntire and Sproull[3]. The precipitate was washed and dissolved in 6 *N* hydrochloric acid, for sample preparation. The radioactivity was determined and the total counts were taken as a measure of synthesis of DNA. The nature of the labelled precursor and the method of precipitation have been considered as an adequate guarantee of the specificity of the method for DNA.

The effect of adding antigen to the incubation medium is shown in Fig. 1. The synthesis of DNA

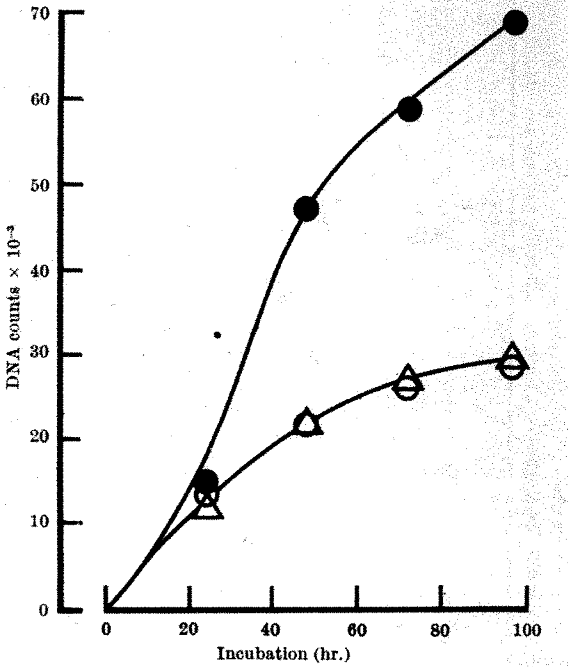

Fig. 1. Antigenic stimulation of DNA synthesis. The rabbit had been previously immunized with human serum albumin. DNA synthesis was measured by the incorporation of ^{14}C-thymidine into DNA. 1 × 10^7 cells were incubated with the following additions to the medium. △, No addition; ●, human serum albumin, 0·5 mgm./ml.; ○, egg albumin, 0·5 mgm./ml. For practical reasons, DNA synthesis was measured for the 24-hr. period prior to collecting individual cultures. The figures, therefore, represent the sums of the appropriate 24-hr. values

Table 1. EFFECT OF ANTIGEN ON THE SYNTHESIS OF DNA IN SPLEEN CELLS FROM PREVIOUSLY IMMUNIZED RABBITS

Incorporation of thymidine into DNA. Total counts

	Protein added to medium				
Antigen used in immunization	None	Egg albumin	Human γ-globulin	Human serum albumin	Bovine serum albumin
None	398	379	453	453	Not done
Egg albumin	331	2,377	735	753	452
Human γ-globulin	4,080	6,350	16,100	12,000	Not done
	775	959	3,040	1,300	Not done
Human serum albumin	10,500	9,560	18,100	32,700	Not done

0·2 μc. ^{14}C-thymidine was added to 1×10^7 cells which had been incubated for 24 hr. in medium containing 0·25 mgm./ml. of the proteins indicated. The cells were collected after a further 24 hr. and the activity in the DNA determined.

falls off in the control culture. In the presence of antigen, however, it increased initially and remained high throughout the period of observation. The 24–48-hr. period was chosen as the most suitable period for further measurements.

The antigen specificity of the stimulation is shown in Table 1. With cells from an unimmunized animal, none of the proteins used stimulated DNA synthesis. With cells from immunized animals there appeared to be some stimulation with other proteins but this was small compared with the stimulation observed with the protein used for immunization. The cross-reaction shown between human γ-globulin and human serum albumin was accounted for by the fact that the preparations had components in common.

The effect of antigen concentration is shown in Fig. 2. Stimulation was observed with less than 1 μgm./ml. In other experiments stimulation appeared to be maximal at 0·1–1 mgm./ml.; but it is not yet known whether this figure is significant or merely reflects some limitation of the incubation conditions. It can be observed that 100 times more human serum albumin was required to give a comparable stimulation to that observed with human γ-globulin.

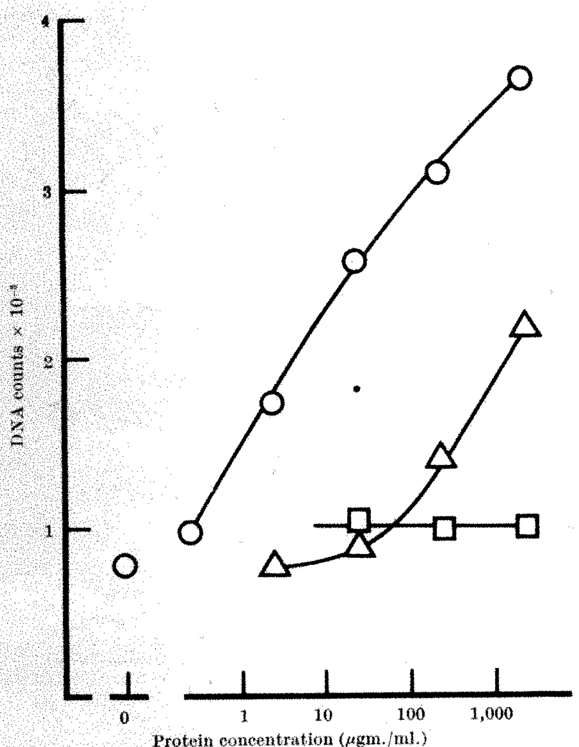

Fig. 2. Effect of antigen concentration on DNA synthesis. The rabbit had been previously immunized to human γ-globulin. The incorporation of ^{14}C-thymidine into DNA was measured over the period 24–48 hr. after the addition of protein. 1×10^7 cells were incubated with the concentrations of protein indicated. ○, Human γ-globulin; △, human serum albumin; □, egg albumin

In these experiments more than 12×10^3 counts may be incorporated into the DNA of stimulated cells incubated with 0·2 μc. of thymidine ($5\cdot3 \times 10^5$ counts in our assay system) at 18·3 mc./m.mole. This represents the utilization of $2\cdot47 \times 10^{-4}$ μmole thymidine for DNA synthesis. If the DNA of one cell is taken to contain 5×10^{-9} μmole of thymidine this incorporation is equivalent to DNA replication by 5×10^4 cells or by 0·5 per cent of the cells in a culture of 1×10^7 cells. This figure represents a minimum value as no account has been taken of the contribution made by unlabelled endogenous thymidine.

Parallel measurements of the incorporation of tritiated thymidine into cells were made on stripping film autoradiographs of smears prepared after incubation. These showed that the increased synthesis of DNA was primarily due to the incorporation of thymidine into an increased number of cells (Table 2).

It is thus clear that the addition of antigen *in vitro* stimulates DNA synthesis and cell division in cell suspensions from rabbits immunized some months previously to the same antigen.

Table 2. COMPARISON OF INCORPORATION OF ^{14}C-THYMIDINE INTO DNA AND ^{3}H THYMIDINE INTO CELL NUCLEI

	^{14}C-Thymidine into DNA (total counts)	Cells labelled (per cent)	Total grain count per 5,000 cells
Control incorporation	3,960	1·1	2,950
Antigen-stimulated incorporation	8,350	2·8	5,370
Ratio stimulated/control	2·1	2·5	1·8

Cells were incubated with 0·25 mgm./ml. antigen for 24 hr. before the addition of thymidine. The cells were collected after a further 24 hr. incubation. Smears and autoradiographs were made of cells incubated with ^{3}H-thymidine and the DNA isolated from cells incubated with ^{14}C-thymidine.

It seems very likely that this response reflects the proliferation of antibody-forming cells which has been shown to follow antigenic stimulation *in vivo*[4] and therefore provides a suitable system for further study.

Gonadotrophic Action of Aldosterone in *Xenopus laevis*

IT has been shown that 11-deoxycorticosterone[1] and related corticosteroids[2] such as corticosterone, 17-hydroxy-11-deoxycorticosterone, 11-dehydrocorticosterone, 17-hydroxy-11-dehydrocorticosterone, hydrocortisone and cortisone will cause ovulation when injected into *Xenopus laevis* in 5–10 mgm. doses.

It has now been found that aldosterone (5 mgm.) also induces ovulation. Like 17-hydroxy-11-dehydrocorticosterone this occurs 12–15 hr. after injection. With cortisone acetate and hydrocortisone acetate ovulation occurs 36–42 hr. after injection. All experiments were performed at 20°.

We thank Messrs. Ciba Ltd., Basle, for a supply of aldosterone.

Distribution of Taste Sensitivity for Phenylthiocarbamide in Yugoslavia

INVESTIGATIONS into taste sensitivity for bitter as a particular hereditary characteristic in man have found their practical application in human, that is, population genetics. Phenylthiocarbamide (PTC) has been found the most reliable among the bitter substances used for discrimination between sensitive persons and insensitive. We believe that of the different methods described[1-3] the most advantageous one is that of Harris and Kalmus[4-7]. In addition to the testing and checking of modes of heredity, the establishment of frequency of tasters and non-tasters, a relation between the sensitivity for PTC and the thyroid diseases has been noted[7,8]. Recently there seem to have been new developments in the interpretation of this relation[9].

The sensitivity for bitter in certain other conditions and circumstances is also being tested[10,11].

However, all work of this kind is based on the data regarding the distribution of tasters and non-tasters in a healthy population of a certain age. We have tested 406 students in the Medical Faculty in Zagreb. The average age was twenty-one years, with equal proportion of sexes (male 201, female 205).

The method used was that of Harris and Kalmus[4-7]. The results are shown in the Table 1. From there it can be seen that sensitivity lies between the fourth and the fifth solution, 66·99 per cent of the tested persons are tasters, and 33·01 per cent are non-tasters, without a significant difference between the sexes. Although the result is within the frequency limits known in some European populations, the percentage of non-tasters is higher than even in the younger persons tested in Yugoslavia[12]. The analysis of the material shown, with regard to the place of birth of persons, shows an increased frequency of non-tasters among people from the area along the Adriatic coast. This has already been noted in the course of other work[13]. According to this analysis the frequency of non-tasters would be lower in the eastern parts of Yugoslavia. This will be the subject of further work.

PATHOLOGY

Interaction between Epithelial and Mesodermal Elements in Anthramine-induced Tumours of the Rat

IN a group of tumours arising in rat skin painted with 2-anthramine I have observed two examples of a compound tumour different in type from those described in previous similar experiments[1-3]. Their essential feature is that a sarcoma forms the stroma of an epithelial tumour. The natural history shows that the carcinoma and the sarcoma begin as separate growths and unite by collision. As a result the cytology and pattern of growth of the two elements are altered; the detail of the changes throws light on the relationship between epithelium and connective tissue, as well as on the process of carcinomatous invasion.

Twelve August rats, six weeks old, were painted twice weekly for 40 weeks with a 1 per cent solution in acetone of 2-anthramine (Aldrich Chemical Co., Inc., Wisconsin) using Lennox's method[2]. At each painting 0·2–0·3 ml. was applied. By the fortieth week the two rats concerned in this communication showed a number of pearly tumours 0·5–1·0 mm. in diameter studded over the almost hairless painted area on the back.

These tumours, microscopically basal-cell carcinomata, grew slowly for some weeks. Then in each rat a firm vascular dermal nodule developed which grew very rapidly, undermining several epidermal tumours and becoming ulcerated. The tumours and a rim of skin around them were excised when they had been present for several weeks.

First Rat. The greater part of the tumour is a fibrosarcoma composed of closely packed rather slender collagen fibres between which are numerous immature fibroblasts. There are very few argyrophilic reticulin fibrils and no fibres that stain with orcein. In the marginal skin a little distance from the fibro-sarcoma there are several basal-cell carcinomata. These arise from pilosebaceous ducts and are arranged in small rounded masses which show no tendency to invade. There are a few histiocytes around the masses and silver impregnation demonstrates reticulin fibrils in relation to them (Fig. 1). There is a distinct basement membrane of periodic acid–Schiff stained material at the margin. One segment of the sarcoma is highly cellular. It has been invaded by strands of basal-cell carcinoma composed of small elongated darkly staining cells. Around the strands the collagen of the sarcoma has been replaced by a mantle of rounded more lightly staining reticulum cells (Fig. 2) which have produced a dense network of reticulin fibrils (Fig. 3). There is a layer of material stained with periodic acid–Schiff reagent around the basal-cell carcinoma strands similar to the basement membrane at the dermo-epidermal junction. The invading epithelial cells penetrate to the lower limit of the sarcoma but do not pass into the normal tissue around it. The invasion and alteration of cytology do not affect the symmetry of the sarcoma.

Second Rat. The sarcoma is composed of large and very primitive cells, many being multinucleated or in a syncytium. They form no collagen or reticulin but lie in a rather amorphous matrix. This tumour is invaded extensively by strands of basal-cell carcinoma which tend to form a network. Many of the cells on the outer side of these strands are arranged in a low palisade, and elongated sarcoma cells are ranged along the border. The tissue in the meshes is myxomatous and the sarcoma cells in it are stellate. The basal-cell carcinoma strands do not invade beyond the limits of the sarcoma. There is no basement membrane or reticulin network at the junction of the carcinoma and sarcoma.

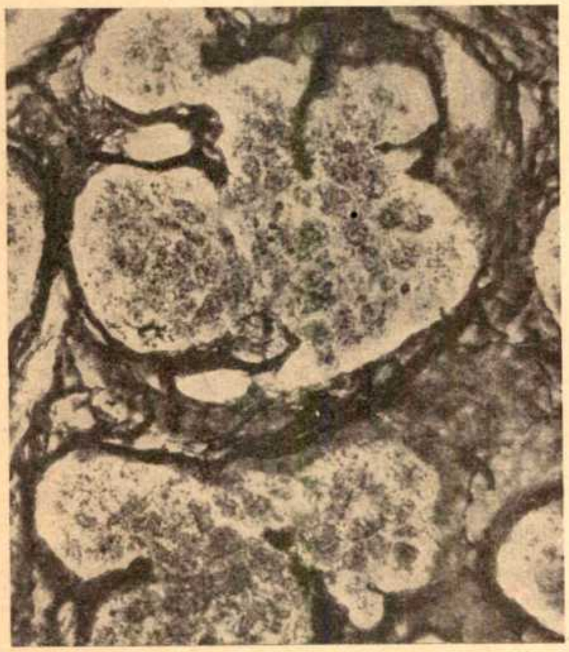

Fig. 1. Nests of basal-cell carcinoma in the dermis with reticulin fibrils surrounding the almost unstained tumour cells. (Robb–Smith silver impregnation. × *c*. 480)

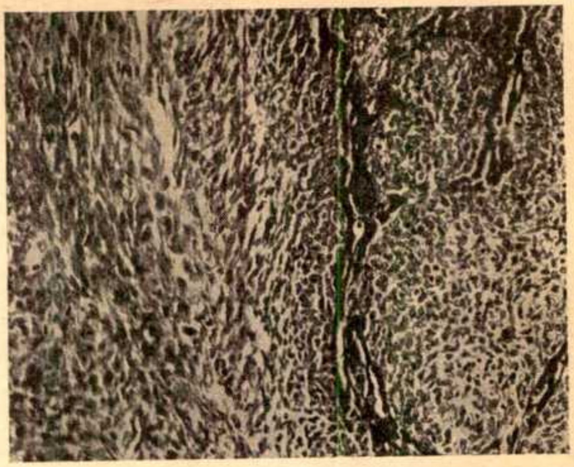

Fig. 2. Invading strands of darkly staining basal-cell carcinoma surrounded by a mantle of reticulum cells. On the left the structure of the fibrosarcoma is shown. (Hæmatoxylin and eosin. × *c*. 126)

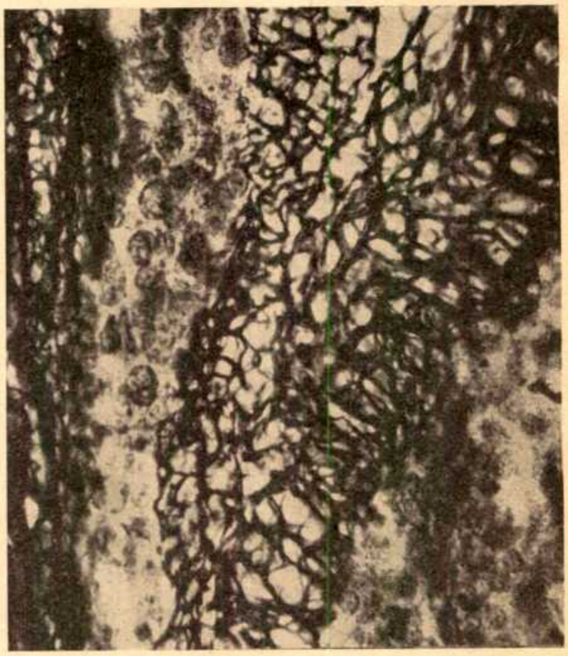

Fig. 3. The cells adjacent to the invading basal-cell carcinoma produce a dense network of reticulin. (Robb–Smith silver impregnation. × *c*. 480)

Tustanovskii and Vasiliev[4] have shown that immature fibroblasts dissolve the collagen around the mammary glands of pregnant mice and form a network of reticulin before the acini begin to proliferate. In the present experiment the same process is seen in the dermis around compact masses of anthramine-induced basal-cell carcinoma. In the fibrosarcoma this mechanism of stroma formation is greatly exaggerated and is associated with enhanced invasiveness of the carcinoma. The train of events is in some respects analogous to the invasion by epidermis of the young connective tissue in healing wounds[5]. In the second sarcoma the primitive cells react to the invading basal-cell carcinoma by forming a mesenchymal type of tissue. In both tumours the carcinoma spreads to the limits of the sarcoma but not out into the surrounding dermis.

Vasiliev[6] has reviewed the evidence relating connective tissue proliferation to invasive growth. He concludes that the formation of undifferentiated connective tissue is essential for the invasion of many malignant tumours, that cancer cells acquire an intrinsic ability to evoke its formation and that their invasive properties may depend on this function rather than on their degree of anaplasia. The behaviour of the two tumours is in keeping with these ideas and also with the view of Kligman and Pinkus[7] that the stroma influences the differentiation and pattern of growth of basal-cell carcinoma and allied tumours.

This work was carried out while I was Roussel Research Fellow.

Sex Chromosomes as Markers in Transplanted Chicken Leukæmic Cells

THE transplantability of virus-induced chicken leukæmia has never been clearly established. If intact cells are transferred to a homologous recipient bird, a leukæmia may develop. This has been interpreted as a transplanted leukæmia rather than the ordinary virus-induced disease mainly on the basis of an unusually rapid course[1,2]. The proof of the ability of leukæmic cells to grow in a homologous host rests, however, on the recognition of donor cells in the recipient. This communication describes the use of sex chromosomes as reliable markers for such a purpose. The technique takes advantage of the fact that male chicken cells contain two sex chromosomes of equal size, whereas the female cells contain only one (Fig. 1).

A suspension of washed spleen cells from a leukæmic male chicken was injected intravenously into five non-inbred female recipients. Strain *R* erythroblastosis virus was used to induce leukæmia in the donor. Aspiration biopsies were taken from the femoral bone marrow of the recipients at the points of time indicated in Table 1. Suspensions of spleen cells were prepared from killed or dead animals. In order to obtain chromosome preparations, bone marrow and spleen cell suspensions were treated according to Moorhead *et al.*[3]. About 20 metaphases were classified as female or male in each preparation. Three of the recipients died from widespread leukæmia on the fourth day after transplantation; the other two showed no outward signs of disease and were killed after 35 days. The organs were grossly normal at autopsy. Table 1 summarizes the results.

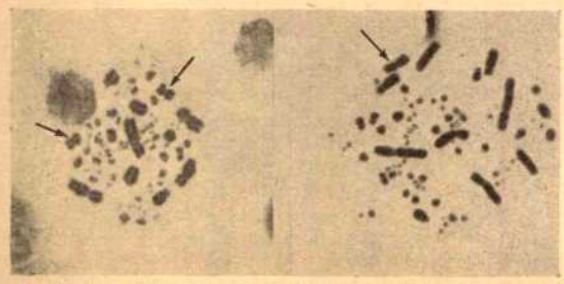

Fig. 1. One male (left) and one female metaphase. The arrows indicate the positions of the sex chromosomes

Table 1. PERCENTAGE OF DONOR (MALE) CELLS IN THE BONE MARROW AND SPLEEN OF FIVE FEMALE RECIPIENTS. $1\cdot2 \times 10^9$ CELLS WERE INOCULATED INTRAVENOUSLY ON DAY 0

	Percentage of donor (male) cells				
	Day 4		Day 21	Day 35	
	Bone marrow	Spleen	Bone marrow	Bone marrow	Spleen
(1) Died day 4 from leukæmia	79	82			
(2) Died day 4 from leukæmia	75	83			
(3) Died day 4 from leukæmia	92	58			
(4) Survived, killed day 35	100		0	0	0
(5) Survived, killed day 35	25		0	0	0

The results show that the transplanted leukæmic cells were able to survive and grow in the homologous hosts. Recipients 1, 2, and 3 succumbed to widespread leukæmia with a high percentage of donor cells in the bone marrow and spleen. Recipients 4 and 5 recovered in spite of the large cell dose used. They both showed a considerable proportion of donor cells in the bone marrow on the fourth day after transplantation. These cells eventually disappeared, presumably due to a homograft reaction.

The technique will be described in detail later. Besides being simple and reliable, it has the advantage of making serial sampling possible from the bone marrow. In this manner, a dynamic picture of the events in individual birds may be obtained.

This investigation was supported in part by a U.S. Public Health Service research grant *C*–4534 from the National Cancer Institute.

HISTOLOGY

Eosinophilic Cells as Possible Mast Cell Precursors

IT is commonly accepted that mast cells in the rat embryo originate from lymphoid-like cells by a process of deposition and numerical increase of cytoplasmic granules, which are basophilic throughout development[1,2].

From an observation on the adult rat which I have made, it seems that another mode of development is possible.

During work on pregnancy changes in the genital tract's connective tissue of the albino rat the presence of numerous peculiar cells was noted. They were seen in the loose connective tissue surrounding the vagina during the early hours after parturition. The cells are localized around small blood vessels (Fig. 1).

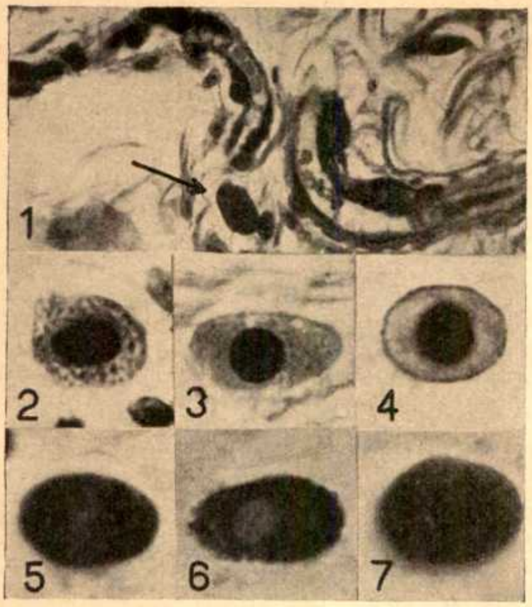

Fig. 1. Eosinophilic cell 4 hr. *post partum* in typical perivascular localization; hæmatoxylin–eosin (× 400)
Figs. 2–4. Eosinophilic cells 4 hr. *post partum* (× 1,200). (2) hæmatoxylin–eosin; the granules are brightly eosinophilic; (3) toluidine blue; the granules do not stain; (4) periodic acid–Schiff; the granules are negative; note the peripheral glycogen granules
Figs. 5–7. Corresponding cells 10 hr. *post partum* (× 1,200). (5) hæmatoxylin–eosin; the granules are bluish; (6) toluidine blue; the granules are intensely metachromatic; (7) periodic acid–Schiff; the granules are periodic acid–Schiff-positive

Their shape is regularly ellipsoid with a central round nucleus. Their most outstanding feature is the presence of numerous uniform, brightly eosinophilic cytoplasmic granules (Fig. 2). With toluidine blue the granules do not stain at all (Fig. 3). The granules have no affinity for the aldehyde–fuchsin stain. The periodic acid–Schiff method does not stain them either, though this technique makes apparent another component: localized at the cell border numerous small glycogen granules are seen. In cross-section these appear as fine strings of beads (Fig. 4). So long as these eosinophilic cells are present not a single mast cell is seen in the whole area.

10–24 hr. after delivery the cells with the above-mentioned characteristics can no longer be seen. Their places in the perivascular spaces seem to be taken by cells which have exactly the same morphology, but have other staining characteristics: in the hæmatoxylin–eosin sections the granules vary from reddish to bluish (Fig. 5). They further exhibit strong metachromasia with toluidine blue (Fig. 6), are periodic acid–Schiff-positive (Fig. 7) and can also be stained with the aldehyde–fuchsin technique.

The description of the second (later) cell type fits well to mast cells.

There are strong reasons for assuming that the two cell types are identical; their morphology and localization are highly similar. Their occurrence is mutually exclusive.

It seems probable that the cells synchronously go through a process of maturation possibly under the influences of endocrinological changes connected with parturition and genital tract involution. During this process the metachromatic granules are formed in two phases: first an eosinophilic (protein) nucleus is laid down; then follows some sort of coating with polysaccharide.

Whether the observed glycogen supplies material for acid mucopolysaccharide synthesis is a matter of conjecture.

IMMUNOLOGY

Immunization against *Schistosoma japonicum* in Rhesus Monkeys produced by Irradiated Cercariæ

In schistosome infection, it has been generally accepted that the antigens for stimulating the production of immune antibodies are the results of the production of eggs in the hosts[1,2]. Recently, we[3] demonstrated that inoculations of rhesus monkeys with the cercariæ of the non-human (zoophilic) strain of *S. japonicum* gave marked protection against a subsequent challenge with its human (pathogenic) strain. Since the non-human strain of *S. japonicum* is usually unable to develop into mature worms in rhesus monkeys, it indicates that the presence of schistosome eggs in the tissues is not necessary for the development of acquired resistance and that the antigens for stimulating the production of potent immune bodies may originate from schistosomulæ. This point of view was confirmed by Sadun *et al.*[4]. The question still remains whether this type of acquired resistance can be produced by the schistosomulæ of the human strain. This can be answered by inoculation of rhesus monkeys with irradiated cercariæ of the human strain before they are challenged with non-irradiated cercariæ.

The cercariæ of *S. japonicum* used were newly shed from the snail, *Oncomelania nosophora*, obtained from Japan. The cercariæ were irradiated in dechlorinated tap-water suspensions 10 mm. deep and 17 mm. in diameter; thus the volume was about 2·25 ml. The vessels containing the liquid were of glass with walls 1·6 mm. thick. The X-irradiation was delivered by a General Electric Maxitron unit. Radiation factors were 250 kVp., 30 m.amp., with 0·25 mm. copper and 1 mm. aluminium filtration. The half-value layer for the beam was 1 mm. copper. The distance from the target to the surface of the suspensions was 248 mm., which yielded an exposure dose-rate of 620 r./min. The total exposure dose given to the cercariæ for immunizing the monkeys was regulated so that the cercariæ were not devitalized but were modified in such a way that they did not develop into adults. It is especially important that female worms become sterile.

The preliminary experiments to determine the critical doses of radiation were performed on albino mice. Sex-determined cercariæ were used. After irradiation, they were transferred to cover glasses. Only the actively swimming cercariæ were used for inoculation, which was given by the cutaneous route with the cover-slip method. Each mouse (18–20 gm.) received 50 male and 50 female cercariæ. The mice were killed 35 days after the inoculation and examined for schistosome worms and eggs.

The rhesus monkeys used weighed 2·1–2·8 kgm. The immunizing inoculation for monkeys consisted of

Table 1. No. of Eggs of *S. japonicum* in the Stools of Immunized and Non-immunized Monkeys

	Inoculation						Eggs/gm. of stool/day	
	Immunizing			Challenge				
					No. of days after:			
Monkey No.	No.	X-ray exposure dose (r.)	No. of cercariæ	No. of cercariæ	First immunizing inoculation	First immunizing inoculation	Maximum	Mean, first 30 days
				Immunized monkeys				
76	3	1,700	8,000	400	154	18	0	0
77	3	1,700	6,000	400	154	40	80	36
82	3	2,000	6,000	400	154	18	30	3
78	4	2,000	9,000	400	154	54	38	17
79	4	2,000	9,000	400	154	18	12	3
				Non-immunized monkeys				
32				400			14,790	1,220
31				400			21,840	4,712
115				400			41,024	12,630
30				400			69,120	6,693
55				400			88,400	46,036

sex-undetermined cercariæ originating from ten or more snails. For the challenge inoculation of immunized monkeys and for the inoculation of control monkeys, only the sex-determined cercariæ were used, each monkey receiving 200 male and 200 female cercariæ. Beginning with the 30th day after the first immunizing inoculation, the stools of each animal were examined daily by the sedimentation method. Because the maximum number of eggs per gram of stool per day during the patent period and mean number of eggs of the first 30 days are usually reliable indices of the intensity of infection of non-immunized and immunized monkeys infected with *S. japonicum* these criteria were used as bases for comparing the two groups.

Albino mice. Six groups of 14 mice each were inoculated with irradiated cercariæ which had been exposed to 2,000 r., 10,000 r., 30,000 r., 45,000 r., and 60,000 r., respectively. Results at autopsy on the 35th day after inoculation showed that presence of immature worms in the group of mice which received 2,000 r., but no worms in the other groups. A second series of experiments followed. Three groups of 6 mice each were inoculated with irradiated cercariæ which were exposed to 500 r., 1,200 r., and 1,700 r., respectively. Results at autopsy on the 35th day after inoculation showed that in the 500-r. group, mature worms and eggs were found; in the 1,200-r. group, male worms with testes and female worms with ovaries but without eggs were found; and in the 1,700-r. group, all the mice harboured only immature worms except one mouse which harboured also one male worm with testes.

Rhesus monkeys. Judging from the results of our preliminary studies on the development of the irradiated cercariæ in mice, cercariæ exposed to 1,700 r. and 2,000 r. were used as the immunizing vaccine against *S. japonicum* in monkeys. The results as given in Table 1 show that in the immunized monkeys the maximum number of eggs per gram of stool per day in the patent period varied from 0 to 80, while in the non-immunized it varied from 14,790 to 88,400. The mean number of eggs of the first 30 days of the patent period in the immunized monkeys varied from 0 to 36, while in the non-immunized monkeys the differences ranged from 1,220 to 46,035. From these results, it may be concluded that inoculations of monkeys with irradiated cercariæ of the human strain of *S. japonicum* gave marked protection against a subsequent challenge with the same human strain.

Recently, Villella *et al.*[5] reported their successes with immunization against *S. mansoni* in albino mice inoculated with irradiated cercariæ. Thus, independently, workers in two laboratories were studying the immunizing effects of irradiated schistosome cercariæ at the same time. It is encouraging that the results of these two investigations closely agree, although they applied to different schistosome species and different hosts. It seems reasonable to infer that pre-inoculation of monkeys with either cercariæ of the non-human strain of *S. japonicum* or irradiated cercariæ of the human strain produce substantial protection against a subsequent challenge with the human strain. As we pointed out previously[3], the two immunization procedures, use of the cercariæ of the zoophilic strain and irradiation of the human strain, may eventually lead to the development of an effective way to combat schistosomiasis.

This investigation was supported by research grants from the National Institute of Allergy and Infectious Diseases, *E*–939, National Institutes of Health, U.S. Public Health Service, and from the World Health Organization.

Effect of Thymectomy on 'Delayed' Hypersensitive Reactions

The thymus is a lymphatic organ the role of which in immune reactions remains unknown. Thymus differs from other lymphatic tissues (lymph nodes and spleen) histologically and in a number of additional characteristics. One of the more interesting observations is that the mass and histology of this organ in germ-free animals are normal despite the markedly reduced mass of conventional lymphatic tissue[1]. The thymus, therefore, appears to develop independently of the antibody-producing organs. However, there is evidence to suggest that the antibody mechanism does not develop normally without thymus. Archer and Pierce[2] found considerable inhibition of antibody production at 8 weeks in rabbits thymectomized at birth. Similarly, there was marked inhibition of subsequent antibody production in chickens from which the bursa of Fabricius was excised at one week[3]. By contrast, bursectomy of 10-week-old chickens[3] or thymectomy of adult rabbits[4] failed to influence antibody production.

The effect of thymectomy on 'delayed' (cellular) hypersensitive reactions has not been investigated

Table 1. DELAYED REACTIONS TO BOVINE SERUM ALBUMIN

Group	Number of rats with reaction*		
	0–5 mm.	6–10 mm.	11–15 mm.

‡ Much of this residual tissue was not thymic.

Table 3. SKIN HOMOGRAFT REJECTION AT 10 DAYS

Group	Number of rats with graft*		
	Not rejected	Beginning rejection	Rejected
Thymectomized	4	5	1
Sham-operated	0	1	3
Unoperated	0	2	5

* Not rejected, homograft is indistinguishable from autograft and from normal skin; beginning rejection, minimal discoloration and swelling; rejected, varying degrees of discoloration and swelling up to total necrosis.

Papermaster *et al.*[5] found evidence that homograft rejection failed to occur in chicks injected on the fifth day of embryonic life with 19 nor-testosterone. This drug prevents development of the bursa of Fabricius, but also, unfortunately, inhibits development of lymphatic tissue throughout the body, and yields under-weight birds, suffering from chronic diarrhœa, which seldom reach adulthood[3]. We wish to present preliminary results showing a striking diminution of several types of 'delayed' reaction in rats thymectomized at birth.

Thymectomy or sternal splitting sham operation was performed on 1–4-day-old Sprague–Dawley rats. Post-operatively thymectomized and control animals gained weight equally, though tending to be slightly lighter than non-operated litter mates. All experiments were carried out in animals 7–10 weeks of age (150–250 gm.). Those failing to gain weight throughout experimentation were discarded.

In the first experiment, rats received crystalline bovine serum albumin (0·5 mgm. in 0·1 ml. complete Freund's adjuvant) in one hind foot-pad, and were tested with the same antigen (30 μgm. in 0·1 ml. saline) between days 8 and 13. Reactions were read at 24, 48 and 72 hr. There was a clear-cut reduction in the delayed response (Table 1), both in diameter and in the degree of induration (not shown in Table 1). Similarly, there was a marked reduction in experimental allergic encephalomyelitis, a disease believed to be mediated by 'delayed' sensitivity[6], in thymectomized rats (Table 2). These animals were injected in one hind foot-pad with 20-mgm. rat spinal cord in 0·1 ml. complete Freund's adjuvant, and observed daily for clinical disease up to 28 days. In another experiment (Table 3), thymectomy appeared to delay the onset and slow the tempo of rejection of skin homografts from Sherman strain rats. Grafts were inspected at 10 days and acceptance or rejection assessed by two observers. The level of circulating lymphocytes in the animals used for the experimental allergic encephalomyelitis experiment was found to be low at the time of inoculation (Table 2). This finding agrees with earlier observations showing both a lowered output of lymphocytes from the thoracic duct and a lowered blood-level of these cells following thymectomy[7].

These experiments emphasize the importance of the thymus in the initiation of delayed hypersensitive reactivity. Thymectomy in early life appears to impair seriously the ability of rats to develop delayed sensitivity to all the antigens thus far tested. The findings in the present study are in accord with immunological evidence, suggesting a relationship between delayed hypersensitivity and the circulating lymphocytes[8].

This work was supported by grants No. *B*-919 and No. *E*-1257 from the National Institutes of Health, and grant No. 268 of the National Multiple Sclerosis Society.

Note added in proof. Since this communication was submitted, Miller (*Lancet*, ii, 748; 1961) has presented preliminary results showing a failure of skin homograft rejection in mice thymectomized at birth, a finding in substantial agreement with our observations on homograft rejection in thymectomized rats.

RADIOBIOLOGY

Radiation Protection of Tissue Culture Cells by Anoxia, Cysteamine and a Combination of Anoxia and Cysteamine

IN the recent literature[1,2] it has been emphasized that the problem whether the radioprotective action of a group of sulphydryl compounds as cysteine and cysteamine is based on the removal of oxygen or is caused by another mode of action on the cellular level is still not solved. In this communication we present evidence in support of the latter hypothesis.

Plating efficiency of cells from an established cell line of human kidney cells[3] was used as a parameter to measure sensitivity to X-irradiation. The cells were plated with Puck's 'feeder-layer' technique[4] in modified Petri dishes consisting of glass rings fitted with a 'Melinex' bottom[5,6]. The cells were allowed to become attached to the 'Melinex' bottom in the incubator before they were treated and irradiated at room temperature. The physical factors of the X-irradiation were 200 kV.; 20 m.amp.;

filtration 1·5 mm. copper; half value layer 1·80 mm. copper; dose-rate 200 r./min. Maximal back-scatter was used.

Cysteamine solutions of a concentration of 4 and 16 m*M* were prepared in tissue culture medium a few minutes before use. The culture medium consisted of 0·5 per cent lactalbumin hydrolysate in Hanks's solution with 5 per cent calf serum; penicillin and streptomycin were added to avoid bacterial infection. The normal medium was replaced by the cysteamine solution 30 min. before irradiation was begun. A few minutes after irradiation the cells were washed three times with normal culture fluid to limit the toxicity of cysteamine. Protection by 4 and 16 m*M* cysteamine is shown in Fig. 1 (curve *b* and *c*). A detailed report on the protection by different concentrations of cysteamine will be published elsewhere.

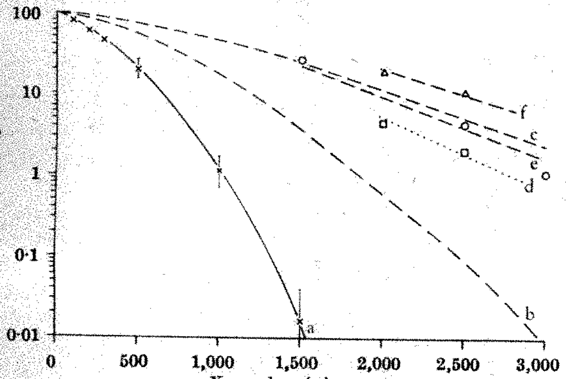

Fig. 1. *a*, Untreated controls; *b*, cysteamine 4 m*M*; *c*, cysteamine ,16 m*M*; *d*, anoxia; *e*, cysteamine 4 m*M* + anoxia; *f*, cysteamine 16 m*M* + anoxia

Anoxic conditions were obtained by flushing over purified nitrogen 10–30 min. before irradiation and during irradiation. For these experiments the glass rings were fitted with a 'Melinex' bottom and top and the rings were provided with a glass inlet and outlet for gas or culture fluid. Before nitrogen was flushed over, the culture fluid was removed. In a Hersch cell[7] connected with the outlet no oxygen could be demonstrated in the gas after the culture had been flushed over for 15 min. Protection by anoxia is shown in Fig. 1 (curve *d*).

The radioprotective action of a combination of anoxia and cysteamine was examined as follows: Cysteamine solution was introduced into a vessel as used for the experiments under anoxic conditions. The solution was removed after 20 min. and immediately afterwards the cells—with adhering fluid containing cysteamine—were flushed over with nitrogen 10 min. before and during irradiation. The results of this combined protection are shown in Fig. 1 (curves *e* and *f*).

In all experiments non-irradiated controls which received the same treatment were used to correct for an eventual slightly toxic action of the treatments.

Cysteamine in concentrations of 4 and 16 m*M* gave dose reduction factors of 1·8 and 3·1 respectively. Under anoxic conditions where no oxygen could be demonstrated a dose reduction factor of 2·5 was obtained. Since 16 m*M* cysteamine gave a higher dose reduction factor than complete anoxia the protective action of cysteamine cannot be explained as an effect caused by anoxia only. This is also shown by the fact that 16 m*M* cysteamine under anoxic condition is giving a better protection than 16 m*M* cysteamine only or anoxic condition only. A third demonstration that the radioprotective action of cysteamine is not caused by an anoxia induced by its autoxidation was found in an experiment in which air instead of nitrogen was flushed over the cells treated with cysteamine. In these circumstances the cysteamine afforded the same protection as under the usual conditions described earlier.

Our results are in close agreement with the results from Kohn and Gunter[8], who found that *l*-cysteine afforded a significant protection of irradiated *Escherichia coli B/r* in suspensions in equilibrium with 0, 5, 20 and 100 per cent oxygen at the time of irradiation.

We thank Dr. A. A. van Soestbergen for the measurements with the 'Hersch' cell.

Phospholipids and the Reaction of Skin to Ultra-Violet Radiation

Investigations are being carried out in these laboratories into the primary photochemical changes in skin caused by ultra-violet irradiation. In the course of this work it was shown that the concentration of phospholipids in mouse skin was significantly decreased following prolonged *in vitro* irradiation at – 20° C.[1-3].

Extremely large doses of ultra-violet irradiation were used in these experiments, however, and to demonstrate the importance of the reaction in the physiological response of skin to such irradiation, a more sensitive technique was used. If phospholipids of the skin are broken down by irradiation *in vivo*, it may well be that following an exposure to ultra-violet there is an increase in the synthesis of phospholipids in the skin exposed. This has been demonstrated by measurements of the incorporation of phosphorus-32 into the phospholipid fraction of irradiated skin.

Albino mice (strain *A*) were used. One ear was exposed to ultra-violet irradiation from a Hanovia medium pressure mercury arc lamp (504/4 type arc tube), at a distance of 1 metre, for a period of 15 min. (dose 1·53 × 10^7 ergs cm.$^{-2}$). The other ear was shielded and used as a control for the subsequent assays. Immediately following the irradiation, 200 μc. of phosphorus-32 were administered to each mouse by intraperitoneal injection. After 24 hr. the mice were killed and the phospholipids extracted from each ear by Schneider's method[4].

The total phosphorus was determined by the method of Berenblum and Chain[5] after complete oxidation of the extracted lipid, and its activity was measured in a liquid counter. The mean specific activity of the phospholipid of the irradiated ear (10 experiments, control expressed as unity) was 1·27, standard deviation 0·165. This increase is highly significant.

The acid-soluble phosphates and the nucleic acids were also isolated and assayed; but the specific activity of these fractions in the irradiated ear was identical to that of the control. This appears to rule out the possibility of our findings resulting from a non-specific effect of irradiation on the metabolic turnover-rate, such as via capillary dilatation.

It is, therefore, suggested that phospholipids may play some part in the primary response of skin to ultra-violet irradiation, and further work is being carried out in this field.

BIOLOGY

Territorial Behaviour in Flocks of Domestic Fowls

THE peck order, observed in domestic poultry flocks, has four main components—aggressiveness, submission, acceptance of submission and recognition. Intra-specific aggressiveness arises as a result of sexual selection for mates, territory and food[1], and submission signals and their acceptance are necessary to divert aggressiveness into harmless channels[2]. Recognition is necessary in a gregarious species to allow these other three forces to be integrated into a peck order. Aggressiveness is only lowered within a group; strangers are always attacked.

Poultry must be well integrated into a stable flock or production is affected[3]. In the large flocks used to-day, it seems unlikely that the birds can recognize and remember all their flock-mates. One way to avoid meeting strangers in a large flock is for individuals to use territorial behaviour to restrict the area of their movements. Each bird would then only meet those birds the territories of which overlap its own.

Regular observations were made on a flock of 80 birds at the University of Queensland Farm at Moggill to record the positions of birds over a period of 41 days in a shed 12 ft. × 36 ft. The areas were plotted on a plan and measured with a planimeter. The average area of movement of birds observed was 137 sq. ft. ± 41 sq. ft., that is, about one-third of the area available.

Further evidence of territorial behaviour was observed when the wire partition between two flocks was removed for three weeks before the flocks were sold. In the initial period many birds crossed the old boundary but were always defeated within a short time (up to ½ hr.) and returned to their own territory. The flock soon settled down with no hens established on the new territory though a few crossed the boundary occasionally. The cockerels of one flock advanced their boundary by about 4 ft. into the other pen, but the two groups did not intermingle freely in this new area.

The fact that birds take up these territories, the areas of which can be measured, suggests that it may be possible to develop a theoretical basis for poultry shed design. This territorial behaviour should be encouraged in large flocks since it reduces the numbers of conflicts when strangers meet. To encourage the tendency to restrict movements, it should be possible to define maximum distances between feeders, waterers and nests so that every bird will have these facilities within its territory.

The hypothesis proposed for this territorial behaviour pattern is based on the number of birds recognized by an individual. The territory size should then be inversely related to the density of birds. This is now being investigated.

A New Type of Cardiac Parasite

A THOROUGH investigation of the ultramicroscopic structure of the frog's heart performed on animals suffering from red-leg disease led to the discovery of very small parasites in the blood-stream and also in the cardiac tissue of two such animals. They accumulated mainly in the sub-endocardial space, that is, the space between the ultra-thin layer of spreading endocardial cells and the sarcolem of muscle fibres. In this space, as previously shown, individual cells, collagen fibres and nerve axons are usually found. The parasites found there in great amounts are a hitherto unknown type of protozoa. The biggest individual specimen found to date measures about 10μ. There are mainly three forms: (1) a pyriform, the biggest of these specimens measured 3μ, having one cilium on its tip; (2) a spindle- or sausage-shaped appearance, having a size of $2–5\mu$ and one cilium on each end; (3) a bizarre type of amœboidal appearance, the biggest of these being up to 10μ in size. They have cilia in irregular distribution stemming from the body.

All these three types are characterized by a membrane surrounding the cytoplasm. This membrane has a thickness of 2–300 Å., and a parallel striation with a rhythmicity of about 500 Å., but no substantial sturdy pellicle is present. In the cytoplasm is an ovoid or spherical nucleus containing a dark karyosome. In the cytoplasm small vesicles and little dark spots can be seen. There is also a most striking parallel arrangement of finest lamellæ showing, at high magnification, a double lining and very small droplets between the lamellæ. The entire group of these lamellæ may be equivalent to a Golgi apparatus or an ergastoplasm or a so-called endoplasmic reticulum. It may also represent the most primitive type of mitochondrium, one lacking surrounding membrane, since in none of the innumerable images of these protozoa which was viewed was a mitochondrium of the usual type present.

The cilia show the typical inner structure of nine fibrils arranged in a circle around a central fibril. Sometimes the membrane surrounding the cilium shows a garland appearance surrounding the skeleton of the inner nine fibrils.

This parasite does not fit into any known species of protozoa. It seems to be the smallest—or at least among the smallest—known, and I therefore suggest for it the name *Ultrazoon ranarum*. It seems probable that further investigation may find that *Ultrazoon ranarum* is not the only representative of this type and that there may be others, too, belonging to this new class. What our investigations have also proved beyond doubt is the fact that part of these intruding parasites are destroyed through phagocytosis by the cells in the sub-endocardial space. It seems that this offers proof that the sub-endocardial cells of a vertebrate have phagocytic properties.

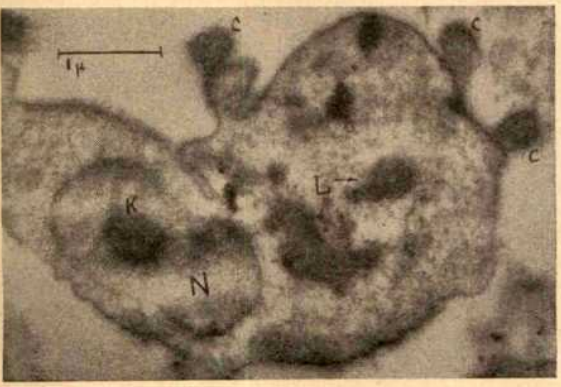

Fig. 1. *Ultrazoon ranarum*. *N*, Nucleus; *K*, karyosome; *L*, two groups of parallel lamels. Notice the small droplets in the cytoplasm and especially at the lamels. (× *c*. 15,000)

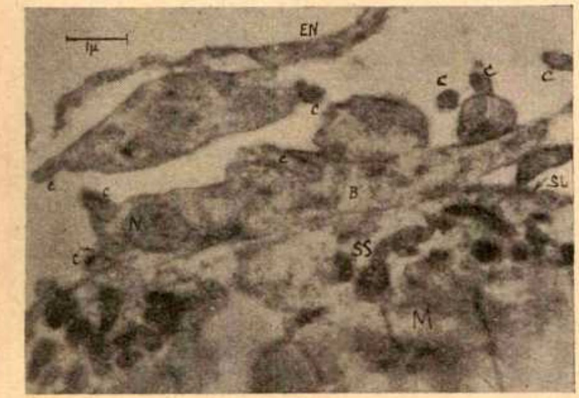

Fig. 2. Group of *Ultrazoa* between the endocard (*EN*) and the sarcolem (*SL*). In the subendocardial space *N*, nucleus, *C*, cilia, *B*, a group of dark dots surrounded by a light circle, as are frequently found near the origin of a cilium. They may be equivalent to the blepharoplast of other protozoa. *SS*, sarcosomes of the heart muscle. *M*, Myofibril. (× *c*. 8,000)

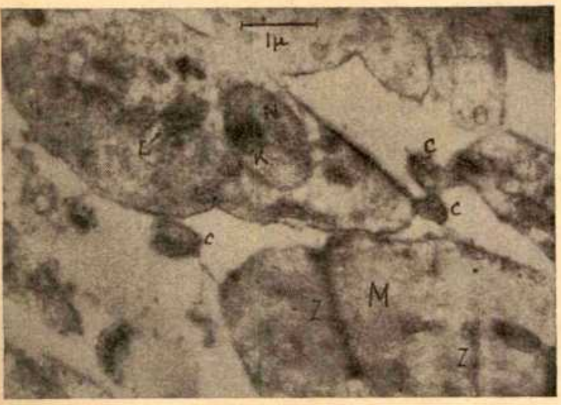

Fig. 3. Group of *Ultrazoa* next to a myofibril near the endocard. *N*, Nucleus; *K*, karyosome; *L*, group of parallel lamels; *C*, cilia; *M*, myofibril; *Z*, *Z*-band of the myofibril. (× *c*. 10,000)

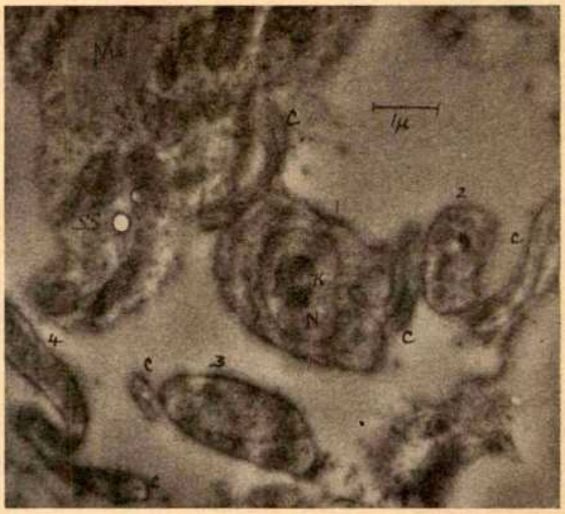

Fig. 4. Group of four *Ultrazoa* near a myofibril (*M*). On top of the myofibril a part of a *Z*-band can be seen. *SS*, Sarcosomes; *C*, cilia. The four *Ultrazoa* are indicated by Nos. 1–4

The findings here reported and Figs. 1–4 may become of interest to human cardiopathology. They should invite electronmicroscopic studies of endocarditis and also electronmicroscopic research into all the other protozoa-mediated diseases.

This investigation was supported by a research grant *H* 4094–*C*2 from the National Heart Institute, National Institutes of Health, U.S. Public Health Service.

Two Morphological Types of Placentæ in the Raccoon

THE literature on the placenta of the raccoon (*Procyon lotor* L.) is extremely sparse and, to the best of our knowledge, placentation in this carnivore is mentioned only by Watson[1], Rau[2], Mossman[3] and Amoroso[4]. The three last-named authors have all quoted aspects of the original contribution by Watson, and it seems, therefore, that knowledge of the raccoon placenta has been based on Watson's early observations. The material at his disposal was, unfortunately, limited to one gravid uterus which contained but one conceptus and, as Watson states, the material was not in the best condition. Observations, in this laboratory, on four gravid uteri involving 17 conceptuses have revealed certain understandable misinterpretations and omissions in Watson's paper. Furthermore, the discovery by one of us (R. F. S. C.)

of a hitherto unreported but prominent placental organ associated with the more commonly mentioned zonary placenta in the raccoon re-focuses attention on the so-called hæmatomata of the carnivore placenta.

The present material was obtained from the reproductive tracts dissected out of 4 pregnant raccoons which had been live-trapped in the spring of 1961 in Pennsylvania. The tracts were fixed in Bouin's solution at the time of killing and stored for later study. Table 1 shows how the conceptuses were disposed in the 4 uteri.

Table 1. DISTRIBUTION AND MEASUREMENTS OF THE EMBRYOS AND PLACENTÆ OF FOUR RACCOONS

(The ranges of the measurements are given in parentheses below each mean)

Animal No.	No. and distribution of embryos		Mean greatest length of embryos (mm.)	Mean width of annulus (mm.)		Mean length of hæmophagous organ (mm.)
	Left cornua	Right cornua		Mesometrial	Anti-mesometrial	
97	2	3	17·8 (16–19)	8·8 (8–10)	15·8 (14–17)	9·3 (8–12)
148	2	2	72·0 (69–75)	25·25 (23–28)	41·75 (36–46)	54·0 (40–62)
142	2	2	74·75 (71–79)	20·0 (19–22)	29·5 (28–31)	40·25 (36–45)
209	2	2	98·25 (94–104)	18·75 (15–21)	27·0 (21–29)	16·25 (0–34)

Subsequent measurements revealed that the material presented a developmental series (Table 1). Nos. 148 and 142 were assessed to have completed 2/3–3/4 of the gestation period while No. 209 was at a near full-term stage of development.

Removal of a window of tissue from the lateral aspect of each locular swelling (Fig. 1) revealed three obvious features within the contained cavity: (1) the embryo within its amnion, with its ventral side facing the mesometrium; (2) an uninterrupted zonary placenta; (3) a prominent and highly vascular organ emerging from a central and anti-mesometrial position of the placental annulus; this prominent structure, for reasons to be discussed here, we propose to call the 'hæmophagous' organ. These three features may be briefly dealt with as follows:

(1) *Amnion*. The amnion, particularly in the more advanced examples, invested the embryo fairly closely in these fixed specimens, and it seems clear that this is the structure which Watson interpreted as an epitrichium.

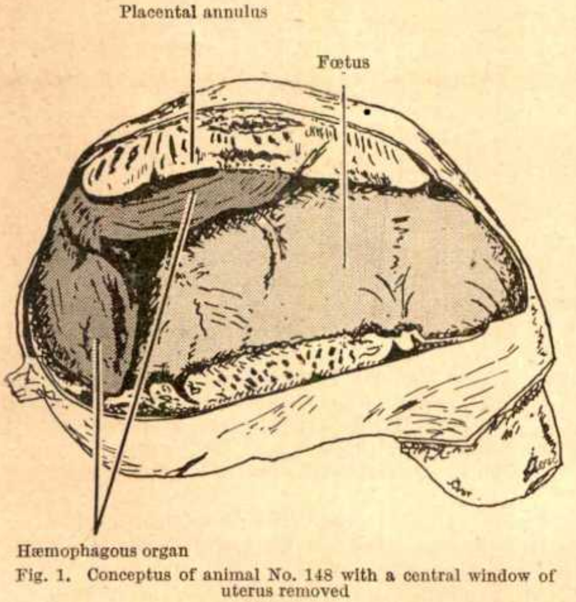

Fig. 1. Conceptus of animal No. 148 with a central window of uterus removed

(2) *Placental annulus*. The raccoon placenta has been described or figured as an incomplete zonary one[1-3]. In no single case of the 17 conceptuses examined in the present work was the annulus incomplete. Histologically, it forms a placental labyrinth, which according to the classification of Grosser would be described as endothelial-chorial. The branching labyrinthine lamellæ consist of fœtal trophoblastic cells surrounding maternal capillaries. These capillaries, which become sinusoid-like as development proceeds, are noteworthy for their atypical endothelium, which is formed of cuboidal cells and resembles the condition of the maternal capillaries of the ferret, the zorille[2] and the wolverine[5]. Fœtal capillaries in the interlamellar fœtal mesenchyme come to assume a sub- and intra-endothelial position with respect to the maternal sinusoidal walls. Thus the fœtal blood approaches very closely to that of the maternal side.

(3) *Hæmophagous organ*. Table 1 shows the developmental history of the hæmophagous organ with respect to size, and Fig. 1 illustrates its position in one of the conceptuses. Emerging from the annulus, its shape for the first half of its length is tubular, while its distal half is expanded and bulbous. The proximal portion runs anteriorly along the dorsum of the embryo, bends first to the right and then to the left over the head of the embryo, the bulbous region resting along the left side of its head and face. Table 1 suggests, however, that the organ grows and then regresses, almost disappearing by full-term. Thus in No. 209 the organ was greatly reduced and in one conceptus was represented by a mere plaque of tissue. Histologically, the hæmophagous organ consists of a highly complex series of branching lamellæ each possessing a fine core of fœtal mesenchyme on either side of which is a single layer of tall columnar fœtal epithelium. Maternal blood, which fills the interlamellar spaces and bathes the fœtal epithelium, gains access through expanded endometrial glands immediately below the organ. This is therefore a hæmochorial condition according to Grosser's classification. Our observations suggest that the cytotrophoblastic tips of the invading fœtal villi erode away maternal epithelium together with much connective tissue and glandular epithelium over the whole placental zone. Except in the region below the presumptive hæmophagous organ, this erosive action continues until the villus tips reach the bases of the glands. In the hæmophagous organ region, however, once the tops of the expanded portion of the glands have been eroded away, the tips of the villi cease their invasive action. This is followed by introversion and proliferation of the trophoblastic epithelium, resulting in the formation of the hæmophagous organ. These epithelial cells are highly columnar with protoplasmic processes on their free surfaces, are gorged with blood cells, granules and other inclusions and bear every sign of great phagocytic activity. A notable feature of these cells is the progressive accumulation within their cytoplasm of pigment material which is presumably a degradation product of hæmoglobin. Fœtal capillaries in the earliest stage (No. 97) have already assumed sub- and intra-epithelial positions with respect to this fœtal epithelium. Thus, in the hæmophagous organ, the maternal blood contents, phagocytosed and transformed by the activity of these

fœtal cells, are in close approximation to the fœtal capillaries.

It seems clear that the raccoon possesses two morphological types of placentæ, an endothelio-chorial one in the labyrinth, and a hæmochorial one in the hæmophagous organ. The terminology of Grosser, however, does not reveal the degree of proximity between maternal and fœtal blood, this proximity being closer in the hæmophagous organ than in the labyrinth in our earliest stage, and of equal closeness in Nos. 148 and 142. The hæmophagous organ in the raccoon may be similar to the "*blutbeutel*" of the otter[6] or the central hæmatoma of the wolverine[5], but development of the placenta in these animals has not been investigated. The term 'hæmatoma' has consistently been assigned in certain animals to regions of the placenta where vascularized chorioallantoic membrane comes into contact with extravasated maternal blood, and the general opinion is that these maternal blood spaces lie between the uterine epithelium and the chorion[3,4]. In the raccoon these blood spaces are not so disposed. Moreover, the term 'hæmatoma' has a pathological connotation which might be misleading when applied to such an 'unpathological' organ. Hæmatomata have also been called accessory placentæ, a term possibly suitable in certain animals but not in the raccoon, where this prominent organ may well be functionally predominant at certain stages of development. For these reasons we have proposed the name hæmophagous organ for a placental structure that consists predominantly of cells of great blood phagocytosing proclivities.

The work was supported by generous grants from the Lalor Foundation and the National Science Foundation (grant No. *NSF G*17658). One of us (R. F. S. C.) also wishes to acknowledge a Fulbright travel fellowship.

Development of Reticulo-endothelial System in Avian Embryos

In spite of the wealth of investigations carried out on the reticulo-endothelial system practically nothing has been reported on its activity and morphology in the embryo. Various workers have noted phagocytosis in early embryonic tissue, but there is divergence of opinion as to the extent and definition of the cells concerned. Recently, Kent[1], using colloidal suspensions of 'Thorotrast' and of silver (silver-110), has made a valuable contribution to the knowledge of the appearance and phagocytic activity of macrophage cells in the chick embryo, and it is to support this evidence further that the present findings are reported.

Investigations were carried out on the chicken embryo using particulate carbon as the indicator of phagocytosis. This method has been previously reported by Nicol[2] as suitable for the assessment of macrophage activity in adult animals; it is dependent on the uptake of carbon of a uniform particle size (250 Å.) when presented in the bloodstream as a colloidal solution. Each egg was injected with the carbon introduced into one of the allantoic veins by means of a fine syringe. The amount of carbon to be injected was determined by the age of the embryo, and was calculated on the basis of 16 mgm. per 100 gm. of body-weight. The egg was incubated for 1 hr. following the introduction of the carbon, then the embryo was removed and sectioned for microscopical examination. Serial sections were obtained, using the cold microtome (cryostat) technique; the sections were stained with weak eosin, alternate slides being counterstained with hæmatoxylin.

These experiments show that the phagocytic activity of the reticulo-endothelial system begins early in embryonic development. At first there is a generalized distribution of cells capable of taking up particulate matter; they are found especially along the vascular pathways which become demarcated by the carbon stored in their lining cells. The liver then develops and takes over as the centre of the phagocytic elements and its sinusoids become clearly outlined as shown in Fig. 1. *a*, *b* and *c*. It is seen that there is a progressive concentration and localization of carbon in the hepatic macrophage cells as the embryo develops, and this without doubt indicates enhanced functional ability. The spleen, owing to its relative smallness, is not prominent as a phagocytic entity until later in embryonic life when its

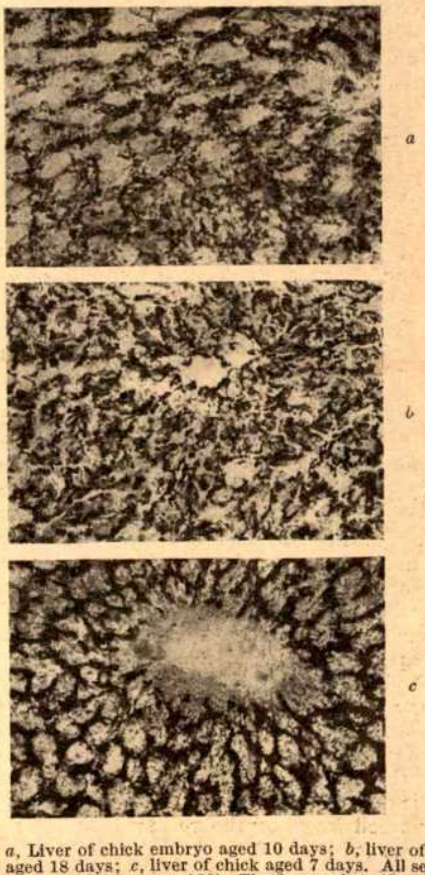

Fig. 1. *a*, Liver of chick embryo aged 10 days; *b*, liver of chick embryo aged 18 days; *c*, liver of chick aged 7 days. All section-stained with weak eosin (× *c*. 100). The figures show the appearance and distribution of the carbon-containing macrophage cells

activity becomes evident by the degree of increased carbon uptake in the phagocytic cells of the pulp. Other sites such as the bone-marrow, the lung and especially the primitive urinary elements also show phagocytic activity, but much less in amount than the liver and spleen, which have been shown to be the principal reticulo-endothelial organs in the adult animal[3].

Research on the physio-dynamics of the reticulo-endothelial system in the embryo is proceeding to associate the embryonic findings with reticulo-endothelial activity and antibody formation after hatching.

Active Secretion of Oxygen into the Eye of Fish

BIOT[1] first described the active secretion of oxygen gas. He found the gas mixture in the swim-bladders of fish captured from great depths in the Mediterranean to consist of 85 per cent of oxygen. At the hydrostatic pressure of 100 atmospheres obtaining at these depths, the partial pressure of oxygen in the swim-bladder must have been 85 atmospheres. Biot announced that the oxygen had entered the swim-bladder through "secretion", and his discovery has been abundantly verified[2-4]. However, no other instances of oxygen secretion have been obtained despite the interest of a number of physiologists, notably Krogh and J. S. Haldane. We have now found large oxygen tensions in the eyes of marine teleosts.

W. N. F. Woodland[5], writing a full century after Biot, was the first to appreciate the essential nature of the gas-producing complex. A glandular area, the gas gland, formed by localized modification of the epithelial cells that line the swimbladder, is supplied with blood from a rete mirabile. This large, discrete organ consists of regular and intimate intercalations of arterial and venous capillaries, which follow parallel courses and carry blood to and from the gas gland. Although there is no proof, several authors[6-8] are of the opinion that the large oxygen tension found in the swim-bladder is built up by the active transport of oxygen from the venous to the arterial capillaries of the rete, and Marshall's[9] description of the secretory complex of abyssal fishes leaves very little doubt that this must be so. Indeed the rete does provide a very large area[10] for exchange of materials.

A similar rete mirabile is found in the choroid layer of the eye of teleost fishes and of the holostean fish, *Amia calva*[11-15]. The choroid rete mirabile supplies arterial blood to the choriocapillaris (the dense capillary network underlying the retina) and in turn receives the venous outflow from these capillaries. Barnett[15] has suggested that the rete might retain within the choriocapillaris some diffusible substance which is essential to vision. It appears to us that the pigment cell layer of the retina is at least formally analogous to the gas gland of the swim-bladder.

Table 1. OXYGEN TENSION IN THE EYES OF MARINE FISH

Species		No. of animals	Oxygen tension Average (range) (mm. mercury)	Rete
Sting ray	*Dasyatus centroura*	2	16 (7–34)	Absent
Skate	*Raja ocellata*	3	10 (6–17)	,,
Smooth dogfish	*Mustelus canis*	3	11 (9–11)	,,
Eel	*Anguilla rostrata*	2	18 (9–23)	,,
Conger	*Conger oceanica*	4	8 (2–12)	,,
Toadfish	*Opsanus tau*	4	18 (6–28)	Minute
Goosefish	*Lophius americanus*	4	93 (39–146)	,,
Sea bass	*Centropristes striatus*	2	161 (130–180)	Small
Tautog	*Tautoga onitis*	1	210	,,
Sea robin	*Prionotus carolinus*	3	468 (280–860)	Large
Fluke	*Paralichthys dentatus*	1	255	,,
Puffer	*Sphaeroides maculatus*	2	462 (365–575)	,,
Scup	*Stenotomus versicolor*	7	484 (272–770)	,,
Menhaden	*Brevoortia tyrannus*	2	255 (240–287)	,,
Goggle eye jack	*Trachurops crumenophthalmus*	4	416 (317–566)	,,
Cod	*Gadus morhua*	3	820 (575–1,180)	,,
Bluefish	*Pomatomus saltatrix*	4	454 (240–820)	Very large
Remora	*Echeneis naucrates*	3	775 (435–1,320)	,,

The structural resemblance between the swim-bladder and choroid retia suggested to us that their functions might be similar, and that the choroid rete mirabile–pigment cell layer complex might serve to create a large tension of oxygen behind the retina, which would provide a pressure head for diffusion to supply the vigorous oxygen demand of the relatively avascular retina. A small oxygen-sensing polarographic electrode (Beckman Spinco Division, No. 161–950 oxygen micro-electrode) was introduced into the front of the eye and passed between the lens and iris into the vitreous humour. The measurements were made on living fish submerged in sea water with a current of sea water passing over the gills. We believe that most of our measurements were made with the sensing tip of the electrode in the vitreous humor immediately in front of the retina. Very large tensions of oxygen were indeed found (Table 1). A variety of bottom-living marine fishes, sea robin, fluke, puffer and scup, and two pelagic fishes, jack and menhaden, exhibited oxygen tensions in the vitreous humor ranging from 250 to 800 mm. mercury. These tensions may be compared with the oxygen tension of arterial blood, which is presumably close to that of sea water, 160 mm. mercury. Two species, the bluefish and remora, deserve special comment. The choroid rete of these fast-swimming, sight-dependent, predaceous animals is so greatly developed that the rear of the eyeball bulges and the rete is rotated 90° from its usual symmetric position. The bluefish tolerates handling poorly, and measurements of the oxygen tension in the eye of this species were at best erratic. The remora, by contrast, is tough and resistant to laboratory insult. Three fish were captured. In two of these we measured oxygen tensions of 1,000 and 1,300 mm. mercury respectively, tensions greatly in excess of 1 atmosphere.

We were led to perform these experiments by the postulate that the choroid rete is concerned with oxygen transport. This postulate may be evaluated by comparison of several species having small retia with the already mentioned forms in which the rete is large. Two bottom-living species, sea bass and tautog, have relatively small choroid retia and exhibit oxygen tensions in the vitreous not too different from air. The goosefish and toadfish inhabit murky bottoms and find their food by chemical or tactile senses. The choroid rete of these species is minute, and the oxygen tension in the vitreous humour is correspondingly low, scarcely exceeding the probable venous oxygen tension. Two teleosts, eel and conger, lack choroid retia. The organ is also absent in elasmobranchs of which we have examined three representatives—smooth dogfish, skate, and sting ray. All five species, which lack retia, exhibit very low oxygen tensions at the retina, less than 30 mm. mercury. The observed correlation between the measured oxygen tension and the extent to which the choroid rete mirabile is developed suggests that the rete plays an essential part in establishing the large oxygen tension at the retina.

Two instances of transport of oxygen gas against a large concentration difference are now known. In each instance a rete mirabile is presumed to be the seat of transport, the gas gland or pigment epithelium playing an unknown but subsidiary part. The interesting question to be resolved is whether oxygen transport is a general property of cells magnified to easily measurable proportions by the rete mirabile acting as a counter-current multiplier[16], or is some special property of the rete-gland complex.

Effect of Concentration of Dissolved Oxygen on Survival of Trout and Roach in Lethal Temperatures

IN the freshwater environment high temperature may be associated with low concentrations of dissolved oxygen, particularly in rivers receiving both heated and oxidizable effluents. Since the toxicity of some poisons is increased by lowering the dissolved oxygen concentration[1] and asphyxial levels of dissolved oxygen are increased by an increase in temperature[2], it is likely that lethal temperatures will be reduced by lowering the concentration of dissolved oxygen. Hitherto the lethal effects of high temperature on fish have been measured in the laboratory at concentrations of dissolved oxygen close to the air saturation value[3,4]; the present work was undertaken to evaluate the effect of low concentrations on such measurements.

Rainbow trout (*Salmo gairdnerii*) (length 4·5 cm. ± 0·4 cm.) and roach (*Rutilus rutilus*) (length 12·3 cm. ± 1·8 cm.) were taken from water at 16° C. in May and acclimatized to 18° ± 0·5° C. for at least three days before being tested. They were not acclimatized to low dissolved oxygen because a preliminary test showed that the survival-time of trout kept in a concentration of 4 p.p.m. and tested at 27° C. was similar (93 min.) to that (102 min.) of fish acclimatized to double this concentration.

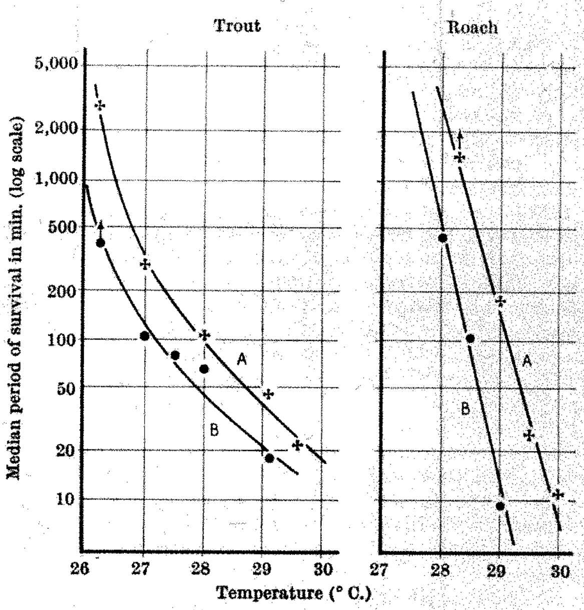

Fig. 1. Survival of trout and roach in lethal temperatures. *A*, Dissolved oxygen concentration, 7·4 p.p.m.; *B*, dissolved oxygen concentration, 3·8 p.p.m.

Tests were carried out in 40-l. aquaria supplied with 1 litre/min. of water at either 7·4 or 3·8 p.p.m. dissolved oxygen, which was obtained by mixing appropriate proportions of air-saturated and nitrogen-saturated water. Trout in batches of ten and roach in batches of five were transferred to the aquaria and the concentration of dissolved oxygen fell by as much as 0·5 p.p.m. and tended to rise again as the fish died. Test temperatures were controlled within 0·1° C. The times of survival of the fish were observed until they had all died or until the tests ended after 24 hr. The individual periods of survival were distributed approximately log normally, and since there was an incomplete kill in some tests the median period of survival was estimated graphically[5].

The relation between these medians and test temperature is shown for both levels of dissolved oxygen in Fig. 1. The survival time of trout and roach is lower at the low concentrations of dissolved oxygen than in the high ones, and though the difference is greater for roach than for trout the amount by which the temperature corresponding to a given period of survival is reduced by lowering the dissolved oxygen is similar for both species, amounting to 0·5° C. at 1,000 min. A fuller account of this and similar work being carried out will be given elsewhere.

B_{12} Coenzyme Content of the Nodules from Legumes, Alder and of *Rhizobium meliloti*

It has been established[1] that cobalt is an essential element for the symbiotic growth of soybean plants and *Rhizobium japonicum* in a purified solution lacking combined nitrogen. It has been shown also that cobalt is needed for alfalfa inoculated with *Rhizobium meliloti*[2]. Legumes supplied with adequate fixed nitrogen do not respond to additions of cobalt[1,2]; but *R. japonicum*, *R. meliloti*, *R. leguminosarum*, *R. trifolii*, and *R. phaseoli* cultured in a purified medium containing both ammonium and nitrate nitrogen failed to grow normally without cobalt[3,4]. The vitamin B_{12} content of root nodules from soybean plants is positively correlated with the cobalt supply in the nutrient medium[1], suggesting that an important role of this element in nodule metabolism is related to that of the vitamin.

Recently, Barker *et al.*[5,6] have isolated a series of cobamide coenzymes which function in the conversion of glutamate to β-methyl aspartate, in the isomerization of methylmalonyl coenzyme *A* to succinyl coenzyme *A* (ref. 7) and in the conversion of 1,2-propanediol to propionaldehyde[8]. Since *Rhizobium* species and symbiotically grown legumes require cobalt for growth it is of obvious interest to determine whether or not these organisms contain the cobamide coenzymes.

Seedlings of alfalfa (*Medicago sativa*, variety Dupuis), soybeans (*Glycine max*, variety Chippewa), peas (*Pisum sativum*, variety American Wonder) and red clover (*Trifolium pratense*, common variety), inoculated with appropriate *Rhizobium* species, were grown in a greenhouse during the summer and autumn in 2-gallon vessels filled with 'Perlite'. Each vessel was supplied every other day with about 500 ml. of a nitrogen-free nutrient solution identical with that described previously[1] with the exception that cobalt, in the form of cobalt chloride, was added at a concentration of 0·05 p.p.m. Cultures were flushed with water on those days when the nutrient solution was not applied. When plants had reached the stages of growth indicated in Table 1, nodules were removed, washed with distilled water and stored at −15° C. until they were analysed.

The B_{12} coenzyme contents of nodules from legumes and alder and of cells of *R. meliloti* were determined by the enzyme assay method of Barker *et al.*[5]. For this procedure, 3–5 gm. of nodules were macerated in 3 vol. of 0·01 *M* potassium phosphate buffer at *p*H 6·5. The coarse material was removed by squeezing through cheese cloth. The liquid was placed in a boiling water bath for 5 min., rapidly cooled in ice and centrifuged at 16,000*g* for 10 min. The supernatant liquid was shielded from light and was used for coenzyme assays.

An extract of *R. meliloti* was prepared from 1 gm. of fresh cells obtained from a pure culture grown in a medium containing the following per litre: K_2HPO_4, 1·00 gm.; KH_2PO_4, 1·00 gm.; $MgSO_4.7H_2O$, 0·36 gm.; $CaSO_4.2H_2O$, 0·13 gm.; $FeCl_3$, 4·00 mgm.; $CoCl_2.6H_2O$, 20·19 mgm.; mannitol, 3·00 gm.; and yeast extract, 1·00 gm. The cells were suspended in 10 ml. of 0·01 *M* potassium phosphate buffer, *p*H 6·5, and prepared by the procedure used for nodules. The glutamate isomerase preparation, which was completely dependent on B_{12} coenzyme for activity, was prepared from *Clostridium tetanomorphum* by the procedure outlined by Barker *et al.*[5]. The coenzyme contents of the various extracts (Table 1) were determined by the glutamate isomerase assay[5] using adenylcobamide coenzyme isolated from *Clostridium tetanomorphum* as the standard. Concentrations of the adenylcobamide coenzyme were calculated, utilizing the molar extinction coefficient of 8·65 × 10^6 cm.^{2} per mole at 458 mμ given by Barker *et al.*[6]. The results in Table 1 are expressed as mμmoles of the dimethylbenzimidazolylcobamide coenzyme. The relative micromolar activity data supplied by Barker *et al.*[6] were used to convert coenzyme concentrations in terms of adenylcobamide coenzyme to concentrations of the dimethylbenzimidazolylcobamide coenzyme.

Table 1. VITAMIN B_{12} COENZYME CONTENT OF THE NODULES FROM LEGUMES AND ALDER AND FROM *Rhizobium meliloti*

Species*	Age	Coenzyme content per gm. of fresh tissue (mμmoles)
Medicago sativa	78 days	347
Glycine max	39 days	231
Glycine max	73 days	116
Pisum sativum	26 days	219
Pisum sativum	45 days	103
Trifolium pratense	81 days	214
Alnus oregona	2 years	174
Rhizobium meliloti	36 hours	290

* Alfalfa plants (age 78 days), soybean plants (age 39 days), peas (age 26 days) and red clover (age 81 days) exhibited initial evidence of flower bud formation. Soybean plants (age 73 days) and peas (age 45 days) showed fully developed flowers. The alder plant, estimated to be 2 years old, was obtained near Corvallis, Oregon, in November 1961 by Mr. Michael Newton.

It is apparent from the results in Table 1 that the concentration of coenzymes in nodules of soybeans and peas during the early flower-bud stage of growth was nearly twice that of nodules from plants that had fully flowered. Nodules of alfalfa contained the highest concentration of B_{12} coenzyme. These results are consistent with Burton and Lochhead's[9] observation that the vitamin B_{12} content of *R. meliloti* was appreciably greater than that of other species of *Rhizobium*. The identification of B_{12} coenzyme in the nodules of alder is of particular interest since it suggests a role of cobalt in a non-leguminous species growing in symbiosis with an actinomycete.

Further investigations were conducted with pure cultures of *Rhizobium meliloti* to determine the identity of the cobamide coenzyme in this organism. The purification and isolation procedures of Barker *et al.*[5,6] were used. The absorption spectrum of a purified preparation isolated from 300 gm. of fresh cells showed peaks at 522–525 mμ, at 375 mμ and an inflexion at 288 mμ. Samples of the coenzyme isolated from *R. meliloti* were chromatographed using secondary butanol, acetic acid and water as the solvents[6]. The R_F values obtained were identical with those of an authentic sample of 5,6-dimethylbenzimidazolylcobamide coenzyme kindly supplied by Dr. H. A. Barker. From the spectral and chromatographic characteristics and from the micromolar activity of the coenzyme in relation to that of authentic cobamide coenzymes in the glutamate isomerase reaction[6] it is concluded that the compound isolated from *R. meliloti* is the 5,6-dimethylbenzimidazolylcobamide derivative. Further experiments are in progress designed to isolate the B_{12} coenzymes from various species of *Rhizobium* and from nodules of symbiotic organisms. Other investigations in progress in our laboratory (De Hertogh, A., personal communication) have shown the presence of methylmalonyl coenzyme A isomerase in extracts of *R. meliloti*.

FORESTRY

Control of *Keithia thujina* Durand by Cycloheximide and Derivatives

Infection of seedlings and transplants of Western red cedar (*Thuja plicata* Lamb.) by *Keithia thujina* Durand frequently causes heavy losses in forest nurseries in Britain. In extensive field control trials carried out over the past ten years, the fungus has displayed a high resistance to a wide range of fungicides. Only copper fungicides showed any effectiveness, but the low level of control did not warrant their general field use. At the present time, *Thuja* is raised by the Forestry Commission by rotation sowing in a small number of nurseries which are isolated from possible sources of the disease. However, effective chemical control is still highly desirable, as avoidance of the disease by rotation sowing requires several economic forest nursery units which are not available to many private woodland owners.

Recent experiments in two Forestry Commission research nurseries, at Alice Holt, Surrey, and Wareham, Dorset, have demonstrated a high level of control of *Keithia* infection on *Thuja* transplants by cycloheximide and three derivatives. The cycloheximide used was in the form of commercial 'Actidione *BR*' concentrate, but the oxime, semicarbazone and acetate derivatives were in crystalline form. 'Actidione' was applied at concentrations of 150 p.p.m. and 50 p.p.m. in a 5 per cent white oil emulsion. The crystalline derivatives were dissolved in a small quantity of dimethylacetamide and made up to concentrations of 150 p.p.m. and 50 p.p.m. in water. 0·02 per cent 'Ethylan C.P.' wetting agent was added to all spray solutions.

In November 1960 at Wareham in a replicated layout of 2 sq. yd. treatment plots of badly infected two-year old transplants, plots were completely sprayed with each material at both concentrations. In March 1961, the same plots were sub-divided, one square yard receiving a further spray treatment, and the other left unsprayed. All solutions were applied at a rate of 300 ml./sq. yd. The experiment was assessed in May 1961, when plants in the unsprayed control plots were showing the late pustule stage of apothecial development on the leaves. Owing to the debilitated condition of the plants, an accurate numerical assessment was not possible, but it was clear that in the half-plots which had received only one spray treatment in November, the level of fresh infection was similar to that in the untreated controls. In the half-plots treated again in March, a high level of control was achieved by all materials at both concentrations. None of the derivatives produced symptoms of phytotoxicity on the transplants, but 'Actidione' at 150 p.p.m. and 50 p.p.m. produced pronounced shoot tip burn symptoms, and at 150 p.p.m. stunting and deformation of unburned parts of shoots were regularly observed.

The absence of control resulting from the November treatment suggests very low, if any, systemic activity of cycloheximide and the derivatives, but the success of the March application indicates excellent protective action against infection produced by the germination, in late March and early April, of ascospores which had overwintered on the surface of the foliage[1].

These experiments are being followed by nursery trials with a range of commercial cycloheximide fungicides at various concentrations, applied at different times.

I thank Upjohn Co., Kalamazoo, Michigan, for the supply of experimental materials, and Mr. D. J. Higgons, Boots Pure Drug Co., Ltd., Lenton Experimental Station, Nottingham, for valuable technical advice.

CYTOLOGY

Colchicine-Type Metaphases in HeLa Carcinoma Cells

Colchicine-like metaphases have been reported recently[1] in human leukæmic leucocytes treated with the dipotassium salt of (ethylene dinitrilo) tetracetic acid and sodium citrate. During a study of the effects of chelating agents on cultured HeLa cells similar metaphases were observed in cultures treated with phosphate-citrate buffer.

Actively growing cells cultured on coverslips in roller-tubes were treated with a preparation of McIlvaine's buffer in isotonic glucose solution. The buffer solution was used at *p*H 7·4. The final concentrations of disodium hydrogen phosphate and citric acid were 2·841 and 0·210 mgm./ml., respectively, in 5·25 per cent aqueous glucose solution. After treatment the cells were thoroughly washed with buffered saline solution and supplied with normal growth medium. This medium was essentially that described by Pereira and Kelly[2].

An abundance of colchicine-like metaphases was found in the cultures 48 hr. after treatment. By this time the cultures had recovered from the acute effects of the experimental treatment. Cells in division at the time of treatment were killed by the buffer solution. Cells with colchicine-like metaphases were enlarged and flattened. They tended to have vacuolated peripheral cytoplasm. Colchicine itself causes bubbling at surfaces of cultured fibroblasts[3]. The chromosomes were usually seen grouped in homologous pairs, well spread and not radially orientated. They were longer and thinner than normal HeLa metaphase chromosomes, stained palely but were structurally intact. Mitotic spindles were not distinguishable in preparations stained with hæmatoxylin and eosin. Most of the metaphases were of the colchicine-type; but other types of mitotic aberrations, including chromosome stickiness and fusion into pyknotic masses, were present. A small percentage of mitoses were normal.

With continued cultivation of the treated cultures the incidence of colchicine-like metaphases decreased while that of other forms of degenerated mitoses increased. In these older cultures the colchicine-like metaphases were highly polyploid and the cells commonly died without entering anaphase. Viable giant interphase cells appeared concurrently with the highly polyploid metaphases and likewise later greatly decreased in number.

Kinlough and Robson[1] obtained colchicine-like metaphases immediately after treatment with the anticoagulants used. In the present experiments the effect was delayed and persisted until the affected cells were eliminated. However, a basic similarity in the mechanisms of the effects is probable. Heparin[4] and another anticoagulant, janus green *B* (ref. 5), have been reported to have a colchicine-like effect on dividing cells. Mazia and Dan[6] isolated the mitotic apparatus of colchicine-treated echinoderm eggs as an amorphous gel, and it was inferred[7] that colchicine affected secondary bonds between individual spindle fibres. These experimental resu'ts are in agreement with Heilbrunn's[4] suggestion that the formation of the mitotic apparatus is essentially dependent on the presence of calcium ions. The delayed effect of phosphate-citrate buffer appears to require a more complex explanation than that for an immediate response during treatment.

Micropinocytosis and Rhopheocytosis

In a recent paper, Brandt and Pappas[1] raise a point of terminology the answer to which appears timely when one considers the present condition of ultrastructural cellular biology.

In his classical work, W. Lewis[2] described a microscopical process of cell absorption different from phagocytosis. As regards this last phenomenon, the first operating factor is known to be adhesion of the cell to the particle it is going to absorb. Once adhesion is achieved and the cell fixed to its prey, the cytoplasm flows, so to say, around it, closes on it and finally incorporates it.

In pinocytosis, the very essence of the mechanism is different. A cytoplasmic veil from the cell, and this, by falling back on the surface of the cell, encloses a droplet from the environment, incorporating it into the cytoplasm in the form of a vacuole (Fig. 1, bottom).

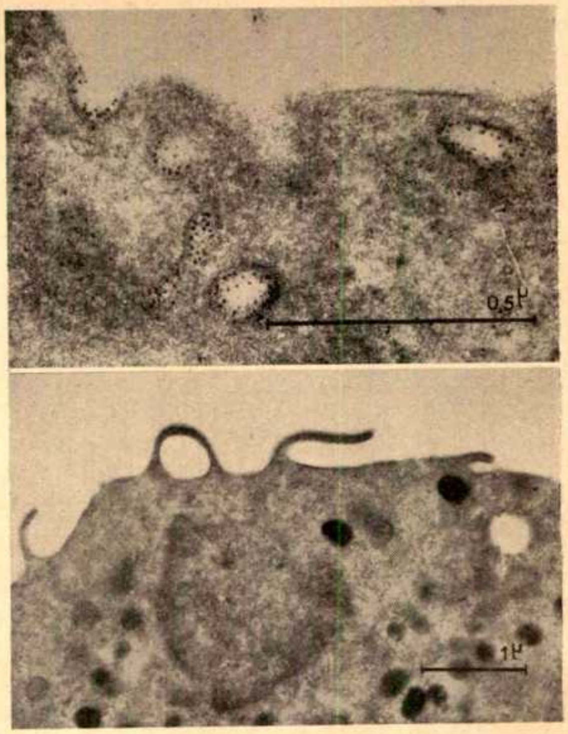

Fig. 1. Above: an example of rhopheocytosis (molecules of ferritin penetrate an erythroblast). Below: an example of micropinocytosis (a polymorphonuclear leucocyte)

Thus pinocytosis, the action of drinking (*pineo*, I drink), and phagocytosis (*phago*, I eat) are differentiated. These facts are well known. While investigating the erythroblasts with the electron microscope, we observed[3,4] the absorption of ferritin molecules fixed to the cellular membrane; we also found them in some of the intra-microscopical depressions of the membrane and again in intra-cytoplasmic vacuoles of the same size as the depressions (Fig. 1, top).

These findings obtained with electron microscopy were obviously of a static order. They were in agreement with those of Palade[5] concerning invaginations of the cellular surface. It therefore seemed reasonable to think of an infra-microscopical absorption mechanism of substances from the milieu. The cell membrane invaginates under the influence of these fixed substances.

By pinching of its edges this invagination becomes a vacuole which sinks into the cytoplasm and becomes part of it with the particles that have led to its formation. In this process, no folding back of a veil takes place and is therefore different from pinocytosis. The phenomenon is termed 'micropinocytosis' and is identical to pinocytosis but on a smaller scale, and only detectable by electron microscopy. For that phenomenon in which no folding back of veils is in action, but in which the cell seems to aspirate the surrounding milieu, we have proposed the name of 'rhopheocytosis' (*rhopheo*, I aspirate).

The phenomenon is of the type of that described by Bennett[6] as 'membrane flow'. As this term is not easy to translate, 'rhopheocytosis' might be preferable.

Akin to rhopheocytosis is the incorporation of hæmoglobin by intra-erythrocytic parasites recently described as phagothrophy[7].

Phagocytosis, pinocytosis, phagothrophy and rhopheocytosis are probably concerned with the same general mechanism. However, in detail, these phenomena are certainly different and we therefore consider it desirable to give them different names.

GENETICS

Immunogenetic Confirmation of the Origin of a Presumed Natural Hybrid between Goldfinch and Greenfinch

A PRESUMED natural goldfinch × greenfinch (*Carduelis carduelis* × *C. chloris*[1]) hybrid was trapped near the town of Parma in September 1960. This bird is the second one captured in these surroundings, the first having been trapped in 1951[2]. The bird answers quite well the description of the goldfinch × greenfinch male hybrids reared in captivity[3]: it has the shape, the size and the heavy, whitish bill of the greenfinch, a small orange mask like the scarlet one of the goldfinch, a yellow wing-bar as in the goldfinch and yellow on the external vane of the primaries as in both of the supposed parental species.

Although, according to Gray[3], presumed natural hybrids have sometimes been reported, absolute certainty of their genetic origin has never been attained. With the aim of identifying beyond doubt the origin of the actual presumed hybrid, an immunological analysis of its red-cell antigens has been made. The inter-relationships of the red-cell antigens of goldfinch, greenfinch and of many other carduelines are well known[4]. Particularly, goldfinch and greenfinch have common antigens and specific ones. According to many researches on F_1 interspecies hybrids, these animals possess both common and specific antigens of the parental species[5].

The red cells of the presumed hybrid were tested by means of anti-goldfinch and anti-greenfinch sera absorbed reciprocally by the red cells of greenfinch and goldfinch, and by the red cells of the presumed hybrid. The immunological technique has already been described[6].

Table 1

Antiserum	Absorbing cells	Test cells		
		Goldfinch	Greenfinch	Hybrid
Goldfinch	Greenfinch	+	−	+
	Hybrid	−	−	−
Greenfinch	Goldfinch	−	+	+
	Hybrid	−	−	−

+, Agglutination; −, no agglutination.

As can be seen in Table 1, the presumed hybrid possesses in its red cells the specific antigens of the goldfinch (shown by anti-goldfinch serum absorbed by greenfinch red cells) and of the greenfinch (made evident by anti-greenfinch serum absorbed by goldfinch red cells). Besides, the red cells of the presumed hybrid contain the antigens common to goldfinch and greenfinch (clearly shown using anti-goldfinch and anti-greenfinch sera absorbed by the cells of the presumed hybrid).

Finally, the presence together of both specific and common antigens of the goldfinch and of the greenfinch in the red cells of this bird clearly indicates that it is a true F_1 hybrid between these two species, this being the unique genetic combination in which all these antigens can be found together.

A New Eye Colour Mutation in *Calliphora erythrocephala* Meig

IN the summer of 1960 a variant eye colour appeared spontaneously in a culture of *Calliphora erythrocephala* which was being kept in the Zoological Institute of the Free University of Berlin. Dr. Peters, a member of the Institute, bred a pure strain from the few mutant individuals and gave us some of their progeny for research.

Until now only one mutation in the eye colour of *Calliphora erythrocephala* had been observed. It was described by Tate[1] and called 'white' (*w*). In the *w*-mutation the eyes of the females alone are a light yellow-orange. This character is both sex-linked and sex-limited and occurs only in double recessive females. The eyes of the new mutant are pure white and are thus very different from the mutation described by Tate, which is also being kept here at the Zoological Institute of Munich. The new character occurs equally in both sexes; it is recessive and independent of the gene *w*. Because of their pure white colour it is suggested here that the name 'chalky' be given to this mutation and that the corresponding gene should be designated by the symbol *c*.

In order to find the source of the white coloration the eyes of the wild-type, of mutant *w* and of mutant *c* females were examined by selective extraction and spectrophotometry for the presence of the main groups of insect eye pigments, the ommochromes and the pteridines.

The ommochromes were extracted quantitatively from the isolated eyes by means of a mixture of methanol and hydrochloric acid[2]. In the case of the wild-type the colour of the extract was red; whereas in both the mutant eyes it manifested almost no absorption above 300 mμ. The difference spectrum, calculated from the absorption curves of the red and the colourless extracts, was compared with the spectra of several different pigments and agreed almost completely with the absorption curve of dihydroxanthommatin. Xanthommatin, the only ommochrome to be found in the eyes of Diptera[3], occurs mainly in the red dihydro-form in living flies. From the difference spectrum it can therefore be concluded that there are no ommochromes in the eyes of the new mutant *c*, just as there was practically none in the mutant *w* under normal breeding conditions[1].

A second mixture, which was prepared from 40 per cent methanol, 1 per cent acetic acid and 59 per cent distilled water, removes pteridines totally and almost exclusively from the tissue. The extracts from the eyes of mutants *w* and *c* had different absorption curves. Between 400 and 430 mμ there was an absorption maximum for the *w*-eyes, whereas there was again no extinction to be found for *c*-eyes above 300 mμ. The difference spectrum for the absorption curves of mutant *w* and *c* shows the main characteristics of the pteridines and is very similar to that of 'sepiapterin'[4]. This light-sensitive derivative of pteridine-6-carboxylic acid is the main pteridine to be found in the eye of *Calliphora*. The pteridine content of mutant *w* does not differ from that of the normal form[5]. The mutant *c*, on the other hand, differs from the wild-type in respect to these substances as well. For this reason a comparative chromatographic and fluorometric test was made (Patat, U., unpublished results), with the result that no fluorescent pigments were to be found in the eyes of mutant *c*. Thus the compound eyes of mutant *c* adults contain none of the pigments characteristic of eyes of insects. The white colour is only of physical origin; most likely it comes from the reflexion of light against the air-filled tracheoles and the background of the eye.

The behaviour of mutant *c* is in complete agreement with the wild-type flies. Although mutant *w* has manifested a diminution of its vitality in several respects, in mutant *c* no such diminution could as yet be found. Through observation of its behaviour, especially in eating and mating, and of the presence of positive phototaxis, one can conclude that the visual sense of these flies is normally developed. The eyes yield the same retinograms as Autrum[6] found in the wild-type and in mutant *w*.

Thus this new mutation in eye colour offers new possibilities for analysis of the significance of pigments in the photoreceptive function of the compound eye. Such investigations are now being conducted[7].

SOIL SCIENCE

Nutrient Enrichment of the Coconut Soils of the Humid Kerala Coast through Monsoon Precipitations

ASSESSMENTS of the agricultural value of the mineral nutrient contents of rain water have been made and recorded in several different geographical and climatic zones of the world[1-12]. Some regions appear to receive appreciable replenishments from the precipitations while in others the amounts so added are comparatively small and of doubtful significance for the nutrient economy of the arable soils of the region. In general, in the equatorial regions nitrogen, including both the inorganic and organic forms, is the element reported as received in appreciable quantities[1,11], although Jones[2] reported rather high figures for potassium (32·8 lb./acre) and sodium (53·8 lb./acre) as well, from Nigeria. The information so far available, however, pertains only to comparatively low and medium rainfall regions.

A preliminary investigation of the nutrient content of rain water was made at this Station, which is in the main coconut belt of the country. The nutritional aspects of the coconut palm, which is purely a rain-fed crop, and the soil fertility factors in relation to palm growth form the main subject of different investigations here. The average annual rainfall of this locality is about 3,750 mm., of which about 75 per cent is usually received during the south-west monsoon, which lasts from about the end of May to the beginning of September, and during the north-east monsoon, which begins during late September and continues up to January. Hence this investigation was confined to the maximum rainfall period. Nitrogen, phosphorus and sodium were determined in the rain water throughout the monsoon period of June–November. The estimate of the potassium content is not included in this communication as complete results are not available. The rain water was collected in the open, care being taken to avoid all possible contaminations by terrestrial dust containing plant or animal debris, atmospheric pollen, etc., during sampling. The analysis was carried out every day in a composite sample and when the rain was scarce it was done after sufficient quantity was collected, the sample under such conditions being preserved by the addition of a little toluene. So far as was practicable the rain water was quite fresh for analysis after collection. The different nutrients were estimated by the Association of Official Agricultural Chemists methods. The results are summarized in Table 1.

Table 1. AMOUNTS OF NUTRIENTS IN THE RAIN-WATER AT KASARAGOD. TOTAL QUANTITY OF RAINFALL RECEIVED DURING JUNE 1–NOVEMBER 30, 1961 = 2,919·7 MM.

Nutrients	p.p.m.	kgm./hectare
Nitrogen		
Ammoniacal	0·44	2·130
Nitrite	0·016	0·076
Nitrate	0·03	0·155
Organic	5·90	27·992
Total (Kjeldahl) nitrogen	6·20	29·779
Phosphorus (P)	0·98	4·748
Sodium (Na_2O)	1·70	8·291

These figures show that the rains do bring down some quantities of nitrogen (mostly in the organic form) and sodium to the soils; the phosphorus content is rather insignificant.

These nutrient materials are received through extremely heavy downpour and a portion of this is likely to be lost through leaching and also surface run off. It is, therefore, not possible to say to what extent these nutrients, particularly the nitrogen, are retained in the soil and utilized by the palms. Indeed, the occurrence of conditions like the foliar yellowing usually observed in the palms during the season actually indicate either nitrogen deficiency in the soil and palms or the impaired utilization of the necessary nutrients due to other conditions. However, a further detailed study of these aspects is being undertaken to obtain a definite idea of the part played by rain in the nutrient economy, particularly of nitrogen, of the coconut soils of rather heavy rainfall areas.

We thank Mr. M. M. Krishna Marar for his advice.

VIROLOGY

Effect of X-Rays on Plaque-forming Ability of Vesicular Stomatitis Virus

The animal virus vesicular stomatitis can be easily propagated in tissue cultures and quantitatively assayed by the plaque-count technique using tissue cell monolayers[1,2]. In preliminary experiments dealing with X-ray inactivation of vesicular stomatitis virus, several morphological plaque-type variants were observed among the irradiated survivors. This observation suggested that vesicular stomatitis virus offers additional material for radiobiological and genetic studies on animal viruses and dictated a quantitative study of the plaque-forming ability of vesicular stomatitis virus when irradiated under a number of conditions suitable for the quantitative estimation and subsequent isolation of plaque-type variants.

The vesicular stomatitis virus strain used was the Ogden isolate, New Jersey antigenic type, kindly supplied by Dr. S. Madin of the Naval Biological Laboratory, University of California, Berkeley. Crude virus preparations were obtained from culture fluid of 24-hr.-old chick embryo cell monolayers[2] previously infected at a multiplicity of 0·2. The culture fluid was centrifuged at low speed to remove bulk host cell debris and then subjected to 38,000*g* at 4° C. for 100 min. The sediment, containing about 95 per cent of the virus, was washed twice in Dulbecco's phosphate-buffered saline[3] by successive centrifugations at 38,000*g*. The final pellet was suspended in phosphate-buffered saline to 10^{10} plaque-forming units/ml. and stored at $-15°$ C. Virus titres generally fell to about 1 per cent of the initial concentration over a six-week period.

The source of X-rays was a Westinghouse Duocondex deep-therapy machine operated at 200 kV., 20 m.amp., 1 mm. aluminium inherent filtration, with an average dose of 1,180 r./min. at the surface of the irradiated suspension. For irradiation, virus samples were thawed (37° C.) and diluted to about 10^6 plaque-forming units/ml. in phosphate-buffered saline, in 1, 10, 15 and 25 per cent 'Difco' nutrient broth or in inactivated 20 per cent lamb serum (final *p*H of each medium, 6·9–7·0). 3·5 ml. samples were irradiated in glass dishes, 2 cm. deep × 3 cm. diameter, centred in the path of the X-ray beam and mounted on a platform which rotated horizontally to the beam during exposure. Except where noted, control and irradiated samples were diluted in the same medium in which they were irradiated, and aliquots of appropriate dilutions seeded in triplicate on 24–30-hr.-old chick embryo cell monolayers grown in prescription bottles[4]. Following 1 hr. for virus adsorption[2], monolayers were overlaid with nutrient agar containing 0·001 per cent neutral red. Plaque counts were made after bottles had incubated at 37° C. for 36–40 hr.

Fig. 1 depicts the effects of X-rays on plaque-forming ability of virus (*a*) irradiated and diluted in phosphate-buffered saline (curve 1); (*b*) irradiated in phosphate-buffered saline and diluted in modified Hanks's solution[5], containing 0·5 per cent lactalbumin; (*c*) irradiated and diluted in 1 and 10 per cent nutrient broth (curves 3 and 4, respectively); (*d*) irradiated and diluted in 20 per cent lamb serum (curve 5). The inactivation of virus in buffer can be attributed to both direct and indirect radiation effects, the latter of which was demonstrated by the inactivation of non-irradiated virus incubated in X-irradiated buffer (47,200 r.) (Fig. 2). A comparison of curves 1 and 2 (Fig. 1) shows that virus irradiated in buffer and diluted in buffer is more sensitive than equivalent virus samples diluted in buffer containing lactalbumin. This post-radiation effect is qualitatively similar to that obtained with bacteriophage[6] and can be accounted for on the basis of long-lived indirect effects which are partially negated by the addition of lactalbumin to the buffer.

Lamb serum and 10 per cent nutrient broth exhibited a pronounced protective effect against X-ray inactivation of virus (curves 4 and 5). Nutrient broth at concentrations of 15 and 25 per cent, although affording protection comparable with that obtained with 10 per cent broth, inactivated control virus rapidly (50 per cent survival) after extended incubation (80 min.). Nutrient broth at a concentration of 1 per cent did not inactivate non-irradiated virus but exhibited only partial protection against X-ray inactivation (curve 3). Thus, either 10 per cent nutrient broth or 20 per cent lamb serum provides maximum protection for the study of direct effects,

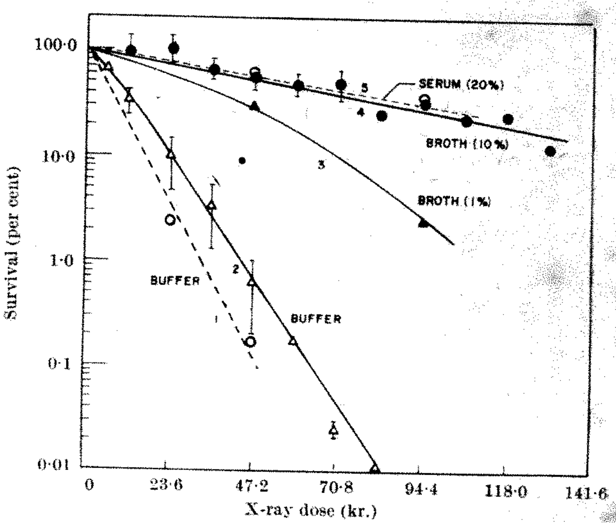

Fig. 1. Effect of X-rays on plaque-forming ability of vesicular stomatitis virus: (1) irradiated and diluted in buffer; (2) irradiated in buffer and diluted in modified Hanks's solution containing 0·5 per cent lactalbumin; (3) irradiated and diluted in 1 per cent nutrient broth; (4) irradiated and diluted in 10 per cent nutrient broth; (5) irradiated and diluted in 20 per cent lamb serum

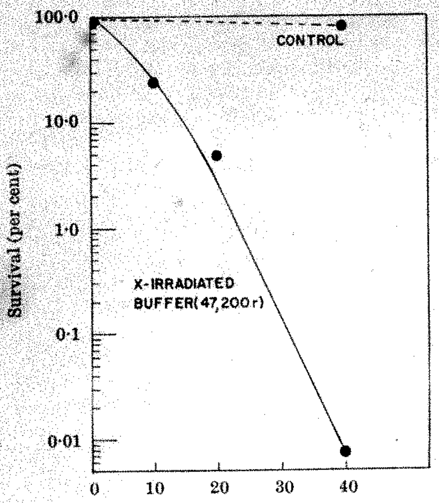

Fig. 2. Inactivation of plaque-forming ability of non-irradiated vesicular stomatitis virus suspended in X-irradiated phosphate-buffered saline

uncomplicated by inactivation of control virus samples. Utilizing the data obtained with 10 per cent nutrient broth, and assuming the inactivation rate of virus under this condition is exponential (Fig. 1, curve 4), the radiosensitive target volume of the virus was calculated using the relation $N/N_0 = \text{exp}^{-VD}$, where N/N_0 is the surviving fraction, V is the radiosensitive target volume (c.c.) and D is the dose in primary ionizations (c.c.) (ref. 7). The dose required to produce 37 per cent survival was 74,000 r. or $4{\cdot}54 \times 10^{16}$ primary ionizations (c.c.). Assuming a single ionization per radiosensitive target volume, $V = 2{\cdot}2 \times 10^{-17}$ c.c. This value is in close agreement with that calculated by Franklin[8] for a Missouri strain of vesicular stomatitis virus irradiated after adsorption. Consequently, the target volume by and large measures the radiosensitive site(s) for infectivity rather than site(s) governing adsorption. If the radiosensitive structure is considered to be a sphere, this volume corresponds to a target diameter of approximately 35 mμ or about 46 mμ by Lea's associated volume method[9], and represents about 4 per cent of the total virus volume assuming a rod of 65 mμ × 165 mμ[10]. The relation between radiosensitive target diameter and the physical virus diameter for vesicular stomatitis virus is similar to that for several large animal viruses[11] in that the former dimension is significantly smaller than the latter.

It should be noted that the plaque count for non-irradiated virus diluted in buffer is lower than that obtained when dilutions are made in broth. Furthermore, the titre of virus suspended in broth may rise on extended incubation (10–40 min.). Microscopic observation of virus samples in buffer and titres of virus samples following vigorous agitation indicate that a proportion of the virus particles forms aggregates in buffer. These aggregates disperse on standing in nutrient broth, thus accounting for the rise in titre of non-irradiated samples. Following low doses of radiation, an apparent increase in survival occurs for virus irradiated in broth if the survival ratio is calculated using the control titre D_0. This increase, however, disappears if the titre of control virus samples at each interval of radiation is used to calculate the survival ratio. If, as suggested by the available evidence, a proportion of the virus particles forms aggregates in buffer, we would predict the survival curve for virus irradiated in buffer to be initially exponential, followed by a 'tail portion' which is multi-hit in character. The failure to obtain this relation (curves 1 and 2) is interpreted to mean that virus aggregates do not serve as infectious units and that the curves depict basically inactivation of single particles.

Virus irradiated in broth was not only less sensitive to inactivation but also formed principally round plaques, while virus irradiated in buffer produced normal, 'ragged', and 'minute' plaques. These results show that irradiation in buffer may provide the most convenient means for the procurement of plaque-type variants.

Purification and Separation of Tobacco Mosaic Virus and Southern Bean Mosaic Virus by Agar-gel Filtration

MOST procedures for the purification and concentration of viruses involve either dense packing of virus particles by sedimentation or by chemical or isoelectric precipitation. Although many viruses can be resuspended easily from pellets or precipitates, others are difficult to resuspend and to separate from contaminants following such treatment. In order to avoid this difficulty we have sought to develop virus purification and concentration procedures which: (1) are very gentle to the virus, allowing it to be retained in suspension throughout the procedures used; (2) require only limited amounts of inexpensive equipment; (3) are capable of handling large volumes; (4) are rapidly and easily accomplished.

Work which we have done on restricted diffusion through agar gels[1,2] led us to the conclusion that, if properly developed, this principle could be used for rapid purification of viruses. Polson[3] recently described the use of columns containing small agar pieces for the separation of proteins. We have examined the use of similar columns for virus purification. We have also explored the possibility of concentrating virus suspensions by ultrafiltration[4]. This communication describes: (1) the use of agar columns and ultrafiltration in the purification and concentration of tobacco mosaic virus and southern bean mosaic virus without chemical or physical 'packing' of the virus; (2) the use of agar columns for the separation of the same two viruses from an artificial mixture.

Suspensions of 'Ionagar No. 2' (Oxoid. This material is mentioned for specific identification only. No discrimination is intended and no guarantee of reliability implied), 4 and 8 per cent by weight in distilled water, are autoclaved for 30 min. at 15 lb. pressure, allowed to gel at 22° C., then chopped into small pieces and sorted by washing through sieves to obtain the fraction which will pass through a 40-mesh but not through a 60-mesh screen.

Glass cylinders are packed with a water suspension of agar chips of the pore size desired. Agar cores are allowed to pack to within 10 cm. from the top of each column and each core is covered with a filter paper disk to prevent disturbance of its surface when various solutions are applied. All columns are washed with sufficient 0·2 M sodium phosphate buffer of pH 7 to remove all traces of soluble material from the agar. The columns used in this experiment had bed dimensions of 2 cm. × 60 cm., 4·5 cm. × 60 cm., and 1·5 cm. × 100 cm.

Fresh tobacco leaves systemically infected with tobacco mosaic virus are dropped into an operating blender containing 100 ml. of buffer (0·2 M sodium dihydrogen phosphate–0·3 M sodium chloride) for each 100 gm. of tissue. Preliminary tobacco mosaic virus suspensions prepared with 0·2 M sodium dihydrogen phosphate had a brown pigment adsorbed to the virus. The pigment can be eliminated by increasing the molarity to 0·5 with sodium chloride. Juice is extracted from the pulp by pressing it through a cheesecloth bag and is then clarified by centrifuging for 30 min. at 500g.

Bean leaves systemically infected with southern bean mosaic virus are similarly ground in a blender with one volume of 0·2 M sodium phosphate–0·1 M ascorbic acid adjusted to pH 7 and one volume each of n-butanol and chloroform. The suspension obtained by squeezing the resulting emulsion through a cheesecloth bag is held overnight at 22° C. and only the upper aqueous phase is retained. Sodium chloride is added to this fraction to bring the total molarity to 0·5. The suspension is then clarified by centrifuging for 30 min. at 500g.

Clarified suspensions of each virus are layered on top of columns of 8 per cent chipped agar (150 ml. can be added to a column 4·5 cm. × 60 cm.) equilibrated with a buffer containing 0·2 M sodium dihydrogen phosphate and 0·3 M sodium chloride, adjusted to pH 6·8 by the addition of sodium hydroxide, and are washed through the columns with the same buffer. Ten ml. samples of effluent liquid are collected until the virus fraction (easily detected by its light-scattering properties) is eluted. The column is allowed to continue flowing until the coloured band of contaminants and all light-scattering material have moved out completely, when it is ready for a new sample.

As virus comes off the 8 per cent agar column it is contained in liquid of at least twice the volume of the crude juice present in the original infected tissue. We have chosen to use ultrafiltration[4] for concentration of these suspensions to between 1/10 and 1/100 of the original volume. The concentrate is clarified for 30 min. at 500g then filtered through a column of 4 per cent agar (2 cm. × 60 cm.) to eliminate a contaminant not separated from either virus by a single passage through 8 per cent agar. The final suspensions are clarified at 500g for 30 min.

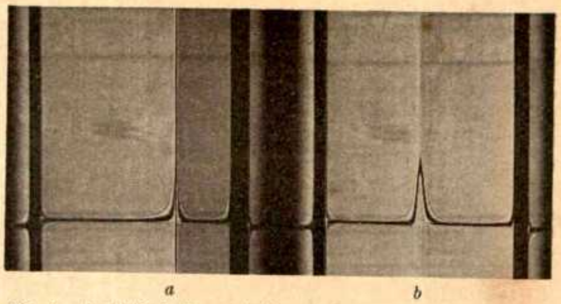

Fig. 1. Analytical ultracentrifuge pattern of virus suspensions purified with agar columns and concentrated by ultrafiltration. (*a*) Tobacco mosaic virus after 32 min. at 20,410 rev./min.; (*b*) southern bean mosaic virus after 40 min. at 20,410 rev./min.

Both tobacco mosaic virus and southern bean mosaic virus purified by the agar column procedure and concentrated by ultrafiltration were colourless and had ultra-violet spectra characteristic of the respective viruses. Each suspension revealed a single peak in the analytical ultracentrifuge (Fig. 1), and electron micrographs showed the expected particles without visible contaminants. Local lesion tests proved that the infectivity of these suspensions was equivalent to that of the same concentrations of these viruses purified by differential centrifugation.

In the development of this new purification procedure we have deliberately used two viruses which are stable and easily resuspended from precipitates or pellets. The method, however, should prove very useful for the purification of those viruses which have been more difficult to work with, and we are now examining this possibility.

Separation of tobacco mosaic virus and southern bean mosaic virus can be accomplished with 4 per cent agar columns in which the agar has a sufficiently large pore size that southern bean mosaic virus can move through, whereas the rod-shaped tobacco mosaic virus is excluded or nearly so. With these columns the tobacco mosaic virus comes off well ahead of the southern bean mosaic virus, and almost complete separation is attained on a 1·5 cm. × 100 cm. column equilibrated with the 0·2 M phosphate, 0·3 M sodium chloride buffers of pH 6·8 (Fig. 2). In this separation process the trailing of both viruses is considerable when 0·2 M phosphate is used.

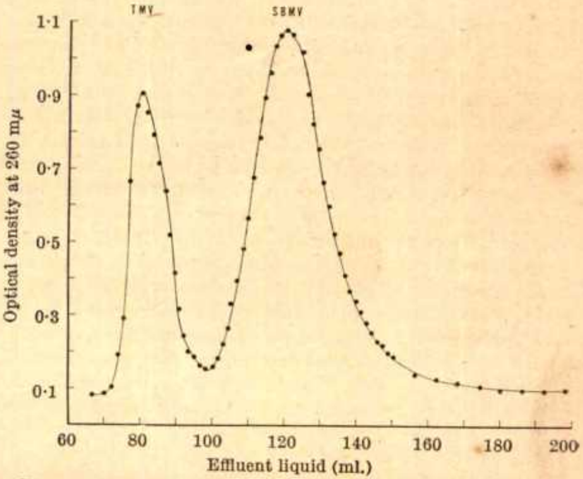

Fig. 2. 'Elution' diagram of a mixture of tobacco mosaic virus and southern bean mosaic virus from a granulated (40–60 mesh) 4 per cent agar column, 1·5 cm. × 100 cm. Ordinate: optical density at 260 mμ

Preliminary tests suggest that columns made up from bottom to top of layers of 8, 7, 6, 5, 4 and 3 per cent agar are superior to those containing only 4 or 8 per cent agar for the separation of particles of different sizes. Additional studies are under way which should give us more information regarding optimum conditions for purification and separation of viruses, cell particulates, nucleic acids, enzymes, and proteins.

We wish to thank Mr. Ralph M. Faust for his excellent assistance in the development of the purification procedure.

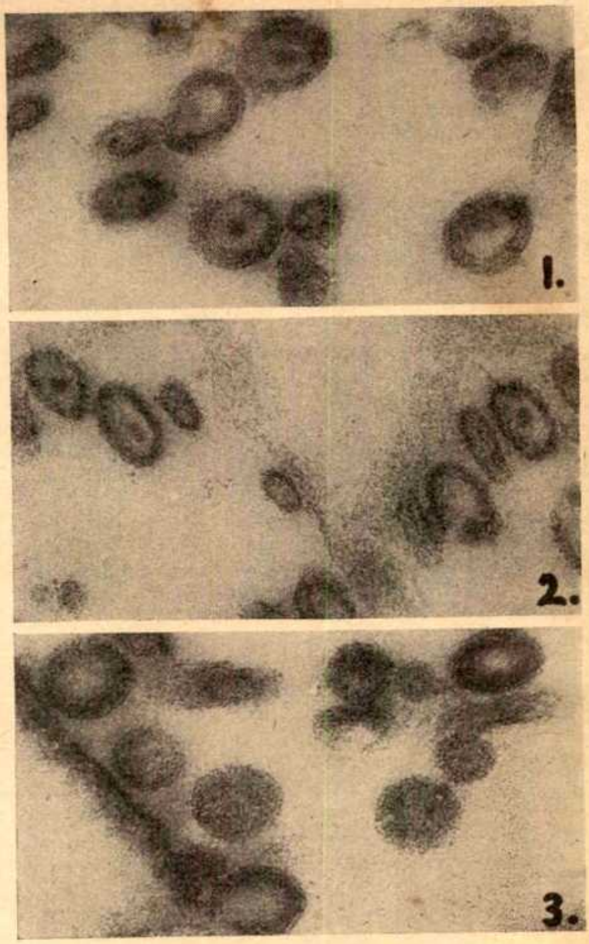
Nucleic Acid of Mature Herpes Simplex Virus: its Type and Location

THE nuclear inclusions of herpes infections have been shown, cytochemically, to contain deoxyribonucleic acid (DNA)[1], and it is further known that this material is synthesized in excess by cells soon after the herpes virus enters them[2]. However, no connexion has been established between the DNA and constituents of the agent, the nucleic acid type of which has not, as yet, been elucidated.

In order to investigate the nature of herpes virus nucleic acid, mature extracellular particles have been treated with specific nucleases, and the resulting changes caused within them have been observed in thin sections with the electron microscope, such methods having proved successful with the adeno and Rous viruses[3]. For the experiments, the *HFEM* strain of herpes was grown in HeLa cultures and the readily recognizable mature virus[4] was gathered along with the cells around which it accumulated. The cells were collected, fixed, dehydrated, embedded in *n*-butyl methacrylate, and sectioned for electron microscopy as already described[5], except that potassium permanganate was used as the fixative[6] since it permits subsequent digestion of nucleic acids by appropriate enzymes[7]. After fixation, samples of the material were placed in iced 30 per cent alcohol and brought to room temperature; the samples were then divided into three groups before continuing with dehydration and embedding. One group was incubated for 2 hr. at 37° C. in 30 per cent alcohol containing 1 mgm./ml. ribonuclease at *p*H 7, a second group was similarly incubated in the same medium containing 1 mgm./ml. deoxyribonuclease together with magnesium chloride (0·003 *M*), and a third group was incubated in the medium containing a similar concentration of this salt but no enzyme.

On examination, the control preparations which had been in the enzyme-free medium all contained numerous extra-cellular particles with well-marked nucleoids (Fig. 1), while the particles in material exposed to ribonuclease also retained these dense structures (Fig. 2). Particles which had been subjected to the action of deoxyribonuclease were quite unlike those of the other groups; their nucleoids were digested, leaving an empty space in the central area (Fig. 3).



Figs. 1–3. Electron micrographs of thin sections cut through permanganate-fixed mature herpes simplex virus particles lying between microvilli close to infected HeLa cells. The particles were treated in various ways before embedding in methacrylate. (× 80,000).

Fig. 1. Control preparation incubated in enzyme-free 30 per cent alcohol for 2 hr. at 37° C. The dense viral nucleoids are present.

Fig. 2. Preparation incubated as the foregoing but with ribonuclease (1 mgm./ml. at *p*H 7) in the alcohol; here, too, the nucleoids are intact, despite some compression of the particles as a result of sectioning

Fig. 3. Particles in a preparation which was incubated with deoxyribonuclease (1 mgm./ml.) and 0·003 *M* magnesium chloride in the alcoholic medium. The nucleoids have all been removed

This finding establishes that herpes virus contains nucleic acid of deoxyribose type and demonstrates that this material is localized, in mature particles, within the viral nucleoid. A full account of these experiments has been reported elsewhere[8].

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, April 9

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. J. T. Kendall: "The Impact of Epitaxial Technique of Semiconductor Devices".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Major E. J. E. Mills: "Two Journeys in Sawt Kohistan".

Monday, April 9—Friday, April 13

International Society for Fat Research (at the Imperial College of Science and Technology, London, S.W.7)—Sixth I.S.F. Congress.

Tuesday, April 10

Society of Chemical Industry, Industrial Water and Effluents Group (at 14 Belgrave Square, London, S.W.1), at 10 a.m.—Symposium on "Re-use of Water in Industry".

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Education or Technical Instruction ?"

Royal Society of Medicine, Psychiatry Section (at 1 Wimpole Street, London, W.1), at 8 p.m.—Prof. O. Ødegaard (Norway): "Psychiatric Epidemiology".

Tuesday, April 10—Thursday, April 12

Faraday Society (at the University, Cambridge)—General Discussion on "Inelastic Collisions of Atoms and Simple Molecules".

Wednesday, April 11

Laboratory Animals Centre (at the Royal Veterinary College, Royal College Street, London, N.W.1), at 9.30 a.m.—Symposium on "The Environment of Laboratory Animals". Chairman: Dr. L. Harrison Matthews, F.R.S.

British Institution of Radio Engineers, Radar Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Mr. E. H. Bruce-Clayton and Mr. D. B. Clemow: "Long Range V.H.F. Air/Ground Communications".

Society of Environmental Engineers (in the Mechanical Engineering Department, Imperial College of Science and Technology, London, S.W.7), at 6 p.m.—Introduced Discussion on "Random Vibration Testing".

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Dr. F. M. Lea: "Development in Building Materials—Prospect for the Future".

Thursday, April 12

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. R. Couteaux: "The Differentiation of Synaptic Areas" (Special Review Lecture).

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. Th. Dobzhansky (Columbia University): "Species in 'Drosophila'" (Hooker Lecture).

Eugenics Society (at 69 Eccleston Square, London, S.W.1), at 5.30 p.m.—Prof. Lars Beckman (University of Uppsala): "Assortative Mating in Man".*

Institution of Electrical Engineers, Utilization Section (joint meeting with the London Joint Group on the Application of Electricity in Aircraft, at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. A. W. Ford: "Brushless Generators for Aircraft—a Review of Current Developments".

Thursday, April 12—Friday, April 13

British Society of Rheology (at the Battersea College of Technology, Battersea Park Road, London, S.W.11)—Conference on "Temperature Effects in Newtonian and Near-Newtonian Materials".

Thursday, April 12—Saturday, April 14

The Anatomical Society of Great Britain and Ireland; The Society for the Study of Human Biology; and The Zoological Society of London (in the Meeting Room of the Zoological Society of London, Regent's Park, London, N.W.1), at 10 a.m. daily—Symposium on "The Primates".

Friday, April 13

Institute of Navigation (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1), at 5.30 p.m.—Captain A. Webster: "The Arrangement of Navigational Equipment in a Modern Cargo Vessel".

Monday, April 16

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Dr. L. G. C. Pugh and Mr. Barry Bishop: "Man at High Altitude".

Society of Chemical Industry, Pesticides Group (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Eighth Annual General Meeting.

Monday, April 16—Wednesday, April 18

British Society of Soil Science (in the New Lecture Theatre, The London School of Economics and Political Science, Houghton Street, London, W.C.2)—Meetings on "Productivity and Soil Type" and "Soil Microbiology".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Leverhulme Student (with a postgraduate diploma in chemical engineering or equivalent qualifications) in Chemical Engineering—The Registrar (University of London), King's College, Strand, London, W.C.2 (April 11).

Lecturer or Assistant Lecturer in Philosophy—The Registrar, University of Singapore, Bukit Timah Road, Singapore 10 (April 14).

Lecturer or Assistant Lecturer in Theoretical Physics—The Registrar, The University, Manchester 13 (April 14).

Research Fellow in the Department of Pure Mathematics—The Deputy Registrar, The University, Edgbaston, Birmingham, 15 (April 15).

Assistant Lecturer or Lecturer in Pure Mathematics—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (April 16).

Lecturer or Assistant Lecturer in the Department of Applied Mathematics—The Registrar, University College of Wales, Aberystwyth (April 18).

Sub-Librarian (Science) (honours graduate, with experience in a university or special library, and preferably with professional qualifications)—The Registrar, University College, Singleton Park, Swansea (April 18).

Senior Lecturer or Lecturer (preferably with a medical qualification) in the Department of Physiology—The Secretary, The University, Aberdeen (April 21).

Lecturer (Grade II) in Philosophy—The Registrar, The University, Bristol 8 (April 25).

Chair of Geography in Fourah Bay College, The University College of Sierra Leone—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 28).

Lecturer (with a good honours degree in mathematics and experience of teaching in schools) in the Department of Education—The Registrar, The University, Liverpool, quoting Ref. CV/40/T (April 28).

Horticulturalist or Botanist, to help in physiological studies on growing plants—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (April 30).

Lecturer in Civil Engineering—The Registrar, The University, Sheffield (April 30).

Plant Physiologist (graduate, or graduating this year, with a good honours degree in an appropriate science), initially for work on bulb crops—The Secretary, Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, Sussex (April 30).

Lecturer or Assistant Lecturer (with a special interest in the plastic deformation or fabrication of metals, and preferably research, teaching or industrial experience) in the Department of Metallurgy—The Registrar, University College, Singleton Park, Swansea (May 1).

Assistant Lecturer (with a good honours degree in mathematics, engineering or physics) in Engineering Mathematics—The Secretary, The Queen's University, Belfast (May 5).

Assistant Lecturer or Lecturer in Applied Mathematics; and an Assistant Lecturer (with qualifications and experience in the general field of physical chemistry, and preferably with a special knowledge of N. M. R. spectroscopy or reaction kinetics) in Chemistry—The Registrar, University College, Singleton Park, Swansea (May 5)

Lecturer (with an honours degree in geography, and preferably with special interests in one of the following fields: climatology, population and settlement studies or urban geography) in Geography at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, May 5).

Senior Lecturer or Lecturer (preferably with research experience in rock magnetism, ionospheric physics, or solid state physics) in Physics at the Royal College, Nairobi—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (May 5).

Lecturer or Assistant Lecturer in the Department of Psychology—The Registrar, The University, Leeds, 2 (May 7).

Lecturer (with a degree or diploma in agriculture, agricultural economics or a related subject and special training in farm management, together with some experience either in teaching or advisory work) in Farm Management—The Principal, Seale-Hayne Agricultural College, Newton Abbot, Devon (May 7).

University Students and Fellows for Experimental or Theoretical Research in Solid State Physics—The Professor of Natural Philosophy, The University, Glasgow, W.2 (May 12).

Esso Student (holding, or expecting to hold, a good university degree in chemical or other branch of engineering, or in chemistry) in Chemical Engineering—The Registrar, University College, Gower Street, London, W.C.1 (May 14).

Assistant Professor (preferably with a Ph.D. or equivalent degree, and experience in research and/or teaching) in Dairy and Food Microbiology—Head, Department of Dairy Science, University of Alberta, Edmonton, Alberta, Canada (May 15).

Lecturer or Assistant Lecturer in Botany and in Physics at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (May 15).

Lecturer in the Department of Biochemistry—The Deputy Registrar, The University, Edgbaston, Birmingham, 15 (May 20).

Baxter Chair of Mathematics—The Secretary, The University, College Gate, St. Andrews, Fife (May 21).

Chair of Biochemistry in the University of Adelaide—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 Australia, May 31).

Denman Baynes Research Student (preferably graduate of the University of Cambridge), to do research in mathematics, physics, chemistry or in an approved related subject—The Master, Clare College, Cambridge (July 1).

Lecturer (between 30 and 50, with a major interest in structural geology and palæontology, and capable of supervising geological field mapping) in Geology at Mandalay University College, Union of Burma—The Director of Recruitment, Department of Technical Cooperation, Carlton House Terrace, London, S.W.1, quoting Ref. RC.203/21/01.

Laurence Reader in Classical Archæology—Secretary of the Appointments Committee, Faculty of Classics, St. Catharine's College, Cambridge.

Master to teach Chemistry to all levels—The Headmaster, Berkhamsted School, Herts.

Research Fellow (with a good degree in physics and some research experience in high energy nuclear physics) for Bubble Chamber Track Analysis—The Deputy Registrar, The University, Edgbaston, Birmingham 15.

Senior Technical Officer (with a degree in agriculture or agricultural botany, or a National Diploma) in the Seed Production Branch—The Secretary, National Institute of Agricultural Botany. Huntingdon Road, Cambridge.

RESEARCH IN INDUSTRY

IN speaking in the House of Lords on November 15, 1961, during a debate on technical and scientific manpower and research, the Minister for Science, Lord Hailsham, while agreeing that the co-operative research associations represented a field in which the Government could possibly do more to foster research in industry, said that he had asked the new chairman of the Council for Scientific and Industrial Research, Sir Harold Roxbee Cox, to make it his special concern to secure a "shake-up" in the research association field. Lord Hailsham himself believed that we had been right to abandon the idea that the research associations could become self-supporting, though he does not agree that there should necessarily be a straight increase in the Government grant. Over the whole field of industry an approach which relied primarily on tax-payers' money as a source of income was doomed to failure, and the need for research was much wider and more universal than could be met in this way.

Lord Hailsham thought that there were several ways in which we could encourage activity in the research associations; but neither the last report of the Department of Scientific and Industrial Research nor that of its Industrial Grants Committee on Research for Industry, 1960, appears to foreshadow the inquiry to which he referred in the House of Lords. Later, on December 5, the development and financing of research associations were discussed in addresses to the Parliamentary and Scientific Committee by Dr. D. W. Hill and Sir Charles Goodeve, while in the report *Industrial Research in Manufacturing Industry, 1959–60*, issued by the Federation of British Industries* also in December, some comments are made by the Federation's Industrial Research Committee on the work of the research associations. Prof. Bruce Williams, in a commentary on behalf of the National Institute of Economic and Social Research, does not discuss the distinctive contribution of the research associations, but the Institute's statistical report considers specifically the use made by industry of the research associations, as well as of the laboratories of the Department of Scientific and Industrial Research. Nevertheless, the Federation's Industrial Research Committee expresses the opinion that the contribution of the research associations is rather unequal and that the situation is unhealthy and merits further investigation from the point of view of industry itself. With this examination of the functions of research associations they would link a re-examination of the research and development problems of small, and perhaps also medium-sized, firms, with the view of stimulating the application of new scientific and technological knowledge.

Dr. D. W. Hill, who dealt with the development of the research associations, their achievements and their importance to the economy, began his address by referring to this instruction of Lord Hailsham to Sir Harold Roxbee Cox to consider afresh and as a matter of urgency the whole question of the development of the associations. The present fifty-two active associations cover some 60 per cent of the productive industry of Britain, and having regard to the very large direct Government expenditure on research and development in such industries as aircraft, electronics, building, civil and mechanical engineering and to the high level of industrial expenditure on research in such industries as chemicals and pharmaceuticals, Dr. Hill does not see much scope for further expansion in numbers. Indeed, it might be observed in passing that present Government policy seems designed to discourage pharmaceutical research. In Dr. Hill's view, the Department's policy should be concentrated on building up and strengthening the existing associations and that it would be unwise to encourage the formation of any new research association without a guaranteed minimum income of £100,000 a year.

Reviewing the achievements of the research associations, Dr. Hill put first, though not necessarily the greatest contribution, the scientific and technical advances produced representing many millions of pounds annually. He gave an estimate of more than £100 million a year in direct benefit to industry to-day from an annual expenditure now running at some £8 million. It is, of course, a matter of argument whether such a return or even a greater return might have attended similar expenditure by industry in its own establishments, for opinion is freely held that, with certain exceptions, the selection of research projects, and often their execution, is most effective within industry itself provided the research establishment has sufficient resources at its disposal.

That reservation could apply in lesser degree to the first of ten other achievements which Dr. Hill lists as immeasurably more valuable though incalculable, but scarcely to the remaining nine. The devising of new and revolutionary techniques that have permitted great advances on a wide front—Dr. Hill instances partition chromatography devised at Torridon, the industrial development of operational research by Tippett at the Shirley Institute and Sir Charles Goodeve with the British Iron and Steel Research Association—is not necessarily a product of co-operative research, but the latter is unquestionably better placed to foster the introduction of a scientific approach into the traditional industries, such as steel, textiles, leather and food, which are still the backbone of British economy, as well as to train personnel in scientific and industrial fields for industry. The educational function of the research associations has yet to receive adequate recognition and it is important that it should not escape the attention of the Robbins Committee. Related to this training for industry is the significant contribution of the many research associations to formal education in collaboration with technical colleges and universities, and Dr. Hill lists with the actual supply of teachers, examiners and senior staff, but separate in its importance, the fostering of the capacity to take broad and industry-wide views. Further, he claims that the research associations have carried out much fundamental research beyond the scope of individual companies and even beyond the interest or ability of universities, and in support cites the publication last year of some 500 papers in scientific periodicals of the highest standards of originality.

---

* Federation of British Industries. *Industrial Research in Manufacturing Industry, 1959–60*: Results of a Survey, including Commentaries and a Statistical Report. Pp. 129. (London: Federation of British Industries, 1961.) 40*s*. (See also *Nature*, 193, 1246; 1962.)

That is undoubtedly a claim to be taken seriously but one that calls for an appraisal of the research associations as a part of Britain's organization for scientific research generally as well as in relation to the structure of higher education. What needs to be examined is the situation, industry by industry, and taking into account the facilities for co-operation in such a research association and in a university or college of technique, particularly where the installation of costly equipment is involved. The point was well made in the recent Zuckerman Report on the management and control of research, and at this point the Industrial Grants Committee obviously must be prepared to concert common policy with the Department's Research Grants Committee.

The last four contributions stressed by Dr. Hill are that the associations have provided unrivalled trouble-shooting service for industry, for large as well as small firms, which has greatly increased efficiency. They have assisted materially in fostering export trade, and here he instanced the contribution of research data supplied by the Spring Manufacturers' Research Association to the design of satisfactory high duty springs in machines for America. The reputations of the associations stood so high abroad that in a dispute between a United Kingdom supplier and a foreign customer their opinion was often accepted without question. The associations had also, as was specially emphasized in *Research for Industry*, 1960, contributed much to health and safety in industry and the community, and finally they were an important source of disinterested and expert advice to many Government Departments.

Dr. Hill's address gave a convincing account of the value of the research associations without necessarily answering the question whether this return could have been obtained with advantage in any other way. He is undoubtedly right as to the comparative neglect of publicity by the research associations, but what is required at this stage is some impartial appraisal not simply of the achievements of the research associations but of the possibilities of achieving a like return by alternative means, or if this is impracticable of increasing the effectiveness of their work. Such an appraisal should precede and not follow the increased support for which both Dr. Hill and Sir Charles Goodeve had pleaded.

Dr. Hill had himself pointed out that between 1920 and 1960 the annual industrial contributions to the research associations had risen from £100,000 to £6·1 million and the Government contribution from £70,000 to £1·8 million; but whereas the industrial contribution had risen by nearly £2·5 million in the past five years, the grant from the Department of Scientific and Industrial Research had only risen by £400,000. Sir Charles Goodeve, who was concerned more especially with the financial aspects, pointed out that two years ago, when the Federation of British Industries made its research survey, Britain was spending on research nearly £500 million, of which two-thirds was Government expenditure, and that of this, half went back to industry for research, mainly in aviation, light electrical engineering and nuclear power. The expenditure of the research associations represented only 1·5 per cent of the total research effort.

Sir Charles included in his paper an analysis of the income of the individual research associations, but when pointing out that in 1960 the £1·8 million grant from the Department of Scientific and Industrial Research represented 23 per cent of the total income compared with 37 per cent in 1950, he based his plea for more generous support on similar arguments to those advanced by Dr. Hill. More particularly, he stressed the value of research associations in fostering the practice of co-operation as well as saving manpower. Drawing on his own personal experience, he thought the structure of the research associations was an important factor in attracting staff of high quality and character who might have been indisposed to enter private industry.

Here Sir Charles enters a field covered by the Zuckerman Report, and his argument must be accompanied by the reservation that to attract staff of such quality and character, it is not sufficient that the conditions of service and the research facilities and equipment should be appropriate. The selection of research projects must also be manifestly wise and worth while, and here again if with Sir Charles we seek to achieve a balanced progress in industry, the problems must be examined comprehensively and objectively, not piecemeal. Neither Dr. Hill nor Sir Charles suggested there were no weaknesses in the research associations, but it is insufficient to identify these and consider them in isolation. The research associations must be considered in relation to our research organization as a whole, and it is in this connexion that it is to be hoped that Sir Charles Goodeve's sensible suggestion that care should be taken to see that the Councils which advise the Government on the distribution of its funds for research include some persons able to speak with direct knowledge of the problems of co-operative research in typical industries served by a research association.

The Federation of British Industries Report gives the expenditure of its members on research and development in 1959–60 as £250 million, excluding capital, and employing 120,000 persons, of whom 28,500 were qualified scientists and engineers, and this expenditure is believed to account for 90–95 per cent of the expenditure on research and development of all manufacturing industry. This applies to research expenditure within the firms: in some industries the picture is changed by the existence of the research associations themselves; for example, only about 5 per cent of the members of the Cotton Industry Research Association and some 20 per cent of the members of the Wool Industry Research Association were members of the Federation of British Industries and probably most of the 21,000 members of the research associations are not direct members of the Federation. Nevertheless, the greater part of the industrial income of the research associations and almost all their sponsored work comes from the larger firms who are members of the Federation. In five industries a substantial income from medium and small firms is derived from a compulsory levy, while in thirteen others some funds are also derived by allocation to research from Trade Associations supported by general subscriptions.

On the industrial use made of research associations, replies to the Federation's questionnaire suggest that perhaps double the proportion of large firms make use of the research associations' facilities compared with medium or small firms, but estimates of the value of the work done for particular firms varied widely. More than 90 per cent of large firms were members of one or more research associations, while among members of the Federation two-thirds of the small firms and more than a third of the medium firms were not members of any research association. Since large firms might be members of up to a score of research associations, comparisons between industries must be accepted with caution, but whereas in chemicals and electrical engineering, which have a high research ratio and very large internal research expenditure, the research associations account for only about 1 per cent of the combined total expenditure on research and development, in some of the traditional industries they may account for more than 40 per cent.

Comments on the work of the research associations frequently referred to the value of information services and informal background discussion, but while a large engineering firm expressed the opinion that practical application of research was more likely to be the direct outcome of their own work rather than that of research done elsewhere, other comment recognized that the research associations could no longer be criticized as too highbrow in their approach to the practical problems of industry, and only in a few industries did critical comments exceed the favourable ones. The former included reference to the need for greater resources to be devoted to the development of new machinery. Comments from the medium-sized or small firms did not support the view that the research associations are mainly of value to the smaller firms nor was there any clear consensus of opinion as to whether there was a substantial number of research projects which are too long-term or too expensive for a single firm which ought to be undertaken by the industry as a whole.

If the statistical report compiled by the National Institute for Economic and Social Research gives little guidance as to the functions or modification of the research associations, comments made by the Federation's Industrial Research Committee are more specific. While the contribution made by the research associations to the overall volume of research in Britain is not large, it includes many examples of first-class work, but a large part of the time of some research associations is devoted to information services and minor *ad hoc* investigations. Useful as these activities are, they cannot replace fundamental investigation, and it might be asked whether such activities could not be organized effectively in some other way.

The unequal level of the contribution made by the research associations revealed by the survey of itself points to the need for some further inquiry, particularly, as the Industrial Research Committee remarks, because the situation is a criticism of industry as of the research associations, which are directed by industrial committees, who may impose limits on the scope of the research. On this point again, the Zuckerman Committee made some comment. Further, the survey, while indicating a demand for improvements in external research facilities, revealed no demand for an increase in the number of research associations or of sponsored research institutes, while it appears also to be true that insufficient use is made in several industries of the research associations and other outside channels for the solution of specific problems. This is mainly true of the traditional industries, though there are others also in which research expenditure is low and there appears to be room for expansion of scientific and technical activity in small and perhaps also medium-sized firms.

On the research associations themselves, Prof. B. Williams's commentary adds comparatively little. He points out that it is not accidental that most of the research associations are in industries that derive little direct benefit from university research, and that while the associations are not simply substitutes for a university, many of them serve industries where both research and development problems are beyond the capacity of the individual firm and that their work must often range from fundamental research to the invention of technical gadgets. He thinks that there are probably certain engineering firms that would benefit from some form of organized contact with a centre of research and development in the appropriate branch of their industry and suggests that the new Machine Tool Industry Research Association, for example, may help to fill this gap in a small, but very important, sector of this industry.

Prof. Williams notes the need in many fields for more systematic dissemination and application of the existing body of knowledge, and his suggestion that more interchange of personnel, seconding of staff, joint work on specific projects and other forms of practical co-operation is in line with observations on these points in the Zuckerman Report on the management and control of research and development. The answers to the questionnaire, he observes, do not, moreover, help us to form a sound judgment as to whether the research associations are undertaking projects on a sufficiently large scale but they do suggest the need for a more co-operative approach to the problem of priorities. The wise selection of targets is of the utmost importance, and if the research associations are to succeed they must be managed by those who possess the necessary experience and sound judgment for taking wise decisions in that matter.

Possibly, as Prof. Williams suggests, the research associations could co-operate more in defining common problems the solutions which would add greatly to the productivity of their work. Apart from this, Prof Williams brings out the extent to which the functioning of the research associations is linked with the supply of qualified scientists and engineers. Any existing shortcomings of the research associations have to be considered in that light, and apart from suggesting that we need more research into the selection of research problems and the question of priorities, Prof. Williams indicates a number of related questions calling for inquiry parallel with those initiated by Lord Hailsham and recommended by the Industrial Research Committee of the Federation of British Industries.

Decisions as to the functions of a research association in any specific context must clearly depend in part on judgments as to the ability of its management to select appropriate targets of research as well as the efficiency with which it uses its qualified manpower. Further consideration of the use of qualified scientific and engineering manpower is needed in industry generally, as Prof. Williams suggests, and not only in the research associations. We need, too, further inquiry into the type of procedures useful in selecting projects in basic research, in applied research and in development, and into the variation of appropriate procedures with the type of activity and between industries. Moreover, the broad question of the function of the research associations and the magnitude of the public support they should receive is a particular facet of the organization of our scientific research effort in general which is at present under consideration by the Advisory Council for Scientific Policy as well as of the establishment of co-operative research institutes generally discussed in the Council's last report. It is to be hoped that the Minister for Science will apply the same mandate of urgency to that inquiry as he has already addressed to that into the research associations by the Council for Scientific and Industrial Research, and it is also to be hoped that the latter Council will be instructed no less firmly to give adequate publicity to the results of that inquiry. If the research associations are to function effectively within whatever limits are determined and to receive adequate public support, both the scientific and industrial world and the general public must be given much more information than has been contained in recent reports either of the Council itself or its Industrial Grants Committee.

METALLURGY OF PLUTONIUM

Plutonium 1960

The Proceedings of the Second International Conference on Plutonium Metallurgy, Grenoble, France, 19–22 April, 1960. Editorial Committee: Emmanuel Grison, William B. H. Lord and Robert D. Fowler. (Organized by Société Francaise de Metallurgie et le Commissariat a l'Energie Atomique.) Pp. xvii + 804. (London: Cleaver-Hume Press, Ltd., 1961.) 189*s*.

INFORMATION on the metallurgy of plutonium has been spasmodic since the Geneva Conference on Atomic Energy in 1958. The Conference, the proceedings of which are reported in this volume, could be described as revealing more information and offering a wider scope than any previous one, and, as such, presented a balanced picture of the subject up to 1960, as claimed by the editors in their preface.

Papers were presented in four sessions, dealing with physical properties, alloys, ceramics and nuclear fuels. The discussions included mention recent developments that have arisen since the writing of the papers, and are fully recorded in the book.

Through the whole proceedings, the question of impurity loomed large. Work on allotropic transformations and physical properties is obviously affected by purity, and one author admitted that the precise position is obscure as a result. The fascinating problem of negative thermal expansion in the delta phase of plutonium has moved a stage nearer to a solution with studies of properties illustrating the density of states at the Fermi surface. Ferromagnetic impurity elements seriously affect low-temperature specific heat, electrical resistivity and thermal expansion and the transformations.

A large number of alloys of plutonium has been investigated in recent years, with a concentration on the theoretical implications. Certain elements have been found to increase the rate of negative expansion of the delta phase in dilute alloys with a reversal of the effect with increasing alloy content. The point at which zero expansion occurs appears to be dependent on electron concentration. The smaller the size of solute metal (within certain limits) the less becomes the minimum amount of solute required to retain the delta phase. Although one might expect that the requirements of nuclear energy would strongly influence a more fundamental approach to alloy theory with respect to such rare metals as plutonium, it is encouraging to read how far this approach is being taken. The effect on metallurgical theory in general is bound to be widespread and welcome.

The chemical metallurgy of plutonium and its alloys is not forgotten, in spite of the extensive effort on the physical problems. Preparation of the metal and atmospheric oxidation are covered in this volume. Production of nuclear fuels, including mixed oxides of uranium and plutonium, and fabrication of fuel elements (chiefly based on alloys with aluminium) appears towards the end. Three papers discuss mechanical properties, two of these including fabrication methods on unalloyed plutonium. Considering the effect of allotropic transformations on this most peculiar metal, it is no small wonder that the measurements of mechanical properties at elevated temperatures give rise to difficulty in interpretation. The energy expended in deformation is bound to cause local changes in temperature, with inevitable repercussions on transformations. The speed of testing is, from these papers, a very pertinent variable.

Two review papers on the use of plutonium in fast fission reactors present the nuclear power facet behind the large experimental and theoretical effort covered in the Conference. Some idea of the tremendous cost involved can be inferred from the statement by one author, discussing fuel element development for one power reactor alone, that 5 million dollars will be necessary. If one multiplies this figure by the number of countries pursuing the same problem, and makes an allowance for variations in method and approach, then roughly 5 million pounds sterling may be a reasonable estimate for the whole world. This should emphasize the importance which the four countries producing significant quantities of plutonium attach to its future use as a nuclear fuel. The present stage of knowledge was very concisely summarized at the Conference, and a measure of the considerable ignorance in which nuclear scientists and engineers are still working. As a direct consequence, the book scarcely requires the recommendation which it deserves.

C. R. TOTTLE

REACTIONS IN ORGANIC CHEMISTRY

Name Index of Organic Reactions

By Dr. J. E. Gowan and T. S. Wheeler. Second Edition. Pp. v+293. (London: Longmans, Green and Co., Ltd., 1960.) 50*s*. net.

ORGANIC chemical processes are often named after their discoverer and this book lists alphabetically no fewer than 739 of such named reactions. A short description of each is given, usually with formulæ, and original papers or reviews are cited from which further information can be gained. There are plenty of cross-references, for example, to related processes, and, where more than one name is associated with a reaction, an entry is found under each. There are a general index based on compounds and also one based on types of reaction. The book undoubtedly satisfies a real demand, in that it provides a guide to the multitude of randomly named reactions that the organic chemist is for ever encountering and enables him to classify them chemically. It is an expanded, and much-improved, version of the author's earlier edition, which had the same title.

Though this book is most necessary, one can only yet again deplore that the need for it has arisen. Though few claim to be in favour of the practice of giving a reaction the originator's name in general chemical usage, very many of us perpetuate it in our writings and, worse, in lectures. The faults of the practice such as obscurity, lack of uniformity in naming, etc., are so well known that detailing here is unnecessary. In this book the name of Claisen is attached by itself to five different processes and, with another name, to seven others, while the name of Baeyer by itself is given to three reactions and, in association, to six others. No fewer than twenty reactions are linked with the name Fischer. With no disrespect to the names involved or to their work, do we really need the following terms in general usage: von Braun–Rudolph modification of the Sonn—Müller reaction, Gryskiewicz–Trochimowski–McCombie–Saunders preparation, Makarov–Zemylanskil–Prokin preparation, Padbury–Lindwall modification of the Grosheintz–Fischer–Reissert reaction ? Reaction No. 630 (the Stacey esterification) was not so called by any wish of its originators, and has never been thus named at Birmingham.

Is it too late to ask that organic chemists describe reactions in chemical terms and give credit to the the discoverers by citing their references ? More realistically, cannot editors of journals refuse to accept named reactions in their publications ? If a few very important processes are linked indissolubly with one name (for example, Grignard reagents), could there not be agreement on a list, as with nomenclature. In fairness to the authors of this book, it is clear from their prefaces that they do not like the practice of giving originator's names to reactions. They are dealing with the situation that already exists, and, as they say themselves, trying to combat the obscurity caused by this undesirable custom.

J. C. TATLOW

SUBSONIC PLANE FLOW

The Theory of Subsonic Plane Flow

By Dr. L. C. Woods. (Cambridge Aeronautical Series, Vol. 3.) Pp. xxii+594. (Cambridge: At the University Press, 1961.) 120*s*. net.

OF all the great scientific disciplines of the twentieth century fluid dynamics takes an honourable place, and if it is not quite such a household word as radioastronomy or nuclear physics, nevertheless its contributions to our modern technological society have been no less revolutionary: the supersonic aeroplane and the guided missile are among the supreme, if misapplied, achievements of man's skill and inventiveness.

The famous physicists of the past century, however, who laid down the immense structure of classical hydrodynamics, as we now call it, made few contributions of real value to twentieth-century technology; for they were perplexed (and knew it) by the effect of the viscosity of the fluids they studied. Certainly they had their successes: as with surface waves (where viscosity is often of negligible importance) and with flow in pipes (where it is overwhelmingly important). But an acceptable theory of flight was beyond their reach and indeed awaited the scientific break-through which eventually came through the genius of Ludwig Prandtl. His conception of the action of viscosity, explained by him in both physical and theoretical terms in 1908, opened the flood-gates of modern aerodynamic research. The boundary layer had arrived !

What, therefore, are we to make of a scholarly book on fluid dynamics which virtually leaves the boundary layer unmentioned and certainly gives it no entry in 6 pages of index ? Is this volume to be regarded as a Victorian phoenix or as a startling *avant-garde* approach ? The former we might well dismiss at once, and with the latter we might sit happily on the fence to see what the future brings. But neither shows the right attitude, for in fact we should most heartily welcome this first exhaustive account of a certain method of solving the two-dimensional Laplace equation under various types of boundary conditions.

For that is what this book is about. It is emphatically not fluid dynamics, nor is it *the* theory of subsonic plane flow as the title claims. There are other theories of compressible (but yet subsonic) flow, many other theories of plane (that is, two-dimensional) flow, even of inviscid, and even more of plane viscous flow. One has very serious doubts as to whether the methods advocated in this book for aiding the solution of real flow problems are, or even will be, in use to anything but a negligible extent.

Nevertheless, this is a fascinating book. The author has indefatigably applied and extended his central idea—namely, the determination, Cauchy-like, of the value of a function in an infinite strip given its real part on one boundary and its imaginary part on the other—to almost every conceivable aeronautical application. It requires considerable discernment to disentangle the wheat from the chaff, the mathematics from the pseudo-physics, which is why I would have preferred a frankly mathematical treatise from Dr. Woods; but the effort is always worth while, and I, for one, am more than grateful for this addition to my shelves.

B. THWAITES

AN INTRODUCTION TO THE ATOM

Modern Atomic and Nuclear Physics

By C. Sharp Cook. (University Physics Series.) Pp. x+296. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1961.) 58*s*. 6*d*.

THIS interesting book, the fifth in Van Nostrand's *University Physics Series*, is intended, we are told in the preface, "for the college or university student who has completed at least one year of classical physics and mathematics through calculus". It attempts to present in a relatively compact book a wide coverage of atomic and nuclear physics.

For the most part it succeeds in giving a clear and up-to-date account of the subject, beginning with gas-kinetic theory, properties of the electron and proceeding by the wave-particle dualism, the Bohr theory and elementary quantum theory to atomic structure and spectra. The coupling of angular momenta of atomic electrons is especially well described. There follows a brief but illuminating introduction to the theory of molecular structure. Solid-state physics and the emission of electrons from solids are described very briefly. The four final chapters deal with nuclear properties, nuclear reactions and elementary particle physics. It is refreshing to find an introductory book on this subject which leads up to the concepts of isotopic spin and strangeness. The only significant omissions are the methods of production and detection of nuclear particles.

However, the inevitable consequence of such coverage is that basic ideas are lost and the reader is forced to be content with much that is empirical. Relativistic mechanics is dealt with in less than eight pages in which we learn little more than the rules of the Lorentz transformation. The book aims to provide "at least a speaking acquaintance with the atom". It is difficult to see what value this has in a physics course in Britain, where emphasis is placed on basic understanding of the subject rather than superficial acquaintance with it. Perhaps it is best recommended as background reading for sixth formers.

The book is marred by a looseness of style and expression, with sometimes unnecessary repetition. Some details should be amended: the mathematical background assumed is sufficient to avoid the use of the Joule classification in the treatment of gas-kinetic theory; a well-known law is incorrectly attributed on page 27; the force on a moving charge is deduced from the force on a current-carrying wire—surely a tautology.

There are 23 pages of problems in the 280 pages of text, and these are probably of little value unless the book is studied in a class. The references given at the end of each chapter are excellent and the keen student will be wise to follow them up.

This is a stimulating and readable book, well illustrated and with clear typography. The subject is presented in an interesting manner, but it is a pity that the author has sacrificed the thorough development which is perhaps more essential in physics than in other sciences.

G. DEARNALEY

ECONOMIC MALACOLOGY

The Giant African Snail

A Problem in Economic Malacology. By Albert R. Mead. Pp. xvii+257. (Chicago and London: University of Chicago Press, 1961.) 7.50 dollars; 60*s*.

STARTING on what may well eventually prove to be a world-wide journey, the giant snail of East Africa, *Achatina fulica*, appears to have reached Madagascar and then Mauritius about the beginning of the last century. From the latter it was carried, presumably by accident, to the Seychelles, but quite deliberately into India by a conchologist, W. H. Benson, who released specimens near Calcutta in 1848. Separate entry from Mauritius took the snail to Ceylon at the beginning of this century and this proved a stepping stone to Malaya and Indonesia. Before the Second World War it had reached the Far East from south China to Japan and had been deliberately introduced into Hawaii and the islands of Micronesia. During the War the Japanese carried it still further.

This was no inconspicuous incomer, unrecognized until too numerous to combat, but a creature worthy of its name, the largest individuals reaching almost 1 ft. when fully extended. With the sole exception of Japan, where winter cold was possibly the deciding factor, attempts at extermination have everywhere failed before reproductive powers potentially capable of producing in three years eight billions (American) from a single gravid snail. In Java more than two million snails and half a million of their eggs were collected by hand in a few weeks.

Dr. Mead has produced a fascinating book of the widest biological interest. He has studied these snails in Africa, Asia and on many Pacific islands. He has also digested relevant information from nearly 900 listed references. He may fairly claim to have succeeded in his declared attempt to produce the first major work on economic malacology. His chapters cover dispersal, economic status, chemical, mechanical and biological control (with enemies ranging from predacious snails to beetle larvæ, giant toads and even hermit crabs) as well as control by human use and legislative action. The problem might be solved if the vast quantities of mucus-encumbered animal protein could be suitably utilized. Dr. Mead comes finally to an interesting consideration of population decline, most probably the result of disease. Taken at the right time, this appears to offer the best hope, if not of extinction, at least of permanent control.

C. M. YONGE

Theory of Elasticity

By V. V. Novozhilov. Translated from the Russian by J. K. Lusher. Pp. xii + 448. (London and New York: Pergamon Press, 1961.) 80s. net.

IN the first part of the book the author develops the theory of elasticity proceeding from the general concept of finite deformation and specializing to cases where (*a*) the strains are small and (*b*) the strains and rotations are small. In this way he examines the geometry of deformation, the conditions of equilibrium, and the strain energy and related concept of virtual work. The classical theory is then examined in detail. Topics considered include the Papkovich solution of the general equations, thermoelasticity, dynamic problems, and existence, uniqueness, minimum, and super-position theorems.

The theory is developed in rectangular Cartesian co-ordinates, but the field equations are also transformed to orthogonal curvilinear co-ordinates. This makes the initial development rather lengthy, but has the effect that many topics in non-linear elasticity become available to the newcomer without resort to tensor notation. The theory of finite deformation is referred to co-ordinates both in the deformed and in the un-deformed body. The careful transition by stages from the non-linear to the classical theory brings out a number of points that are sometimes overlooked in more sophisticated treatments. The book includes a brief mention of tensor notation.

The last two chapters are concerned with problems in classical elasticity. St. Venant's theory of torsion is developed and applied to the twisting of rods of circular, elliptical, triangular, square and other cross-sections. Bending theory is treated similarly. The theory of classical plane strain and stress is formulated in curvilinear co-ordinates and in complex forms. A number of problems is treated using the method of complex power series expansions, aided where necessary by conformal transformations. These include the plane deformation of an infinite plate containing circular, elliptical and (approximately) square holes. The half plane problem is also considered. The book does not deal in any detail with anisotropic bodies or with three-dimensional problems. The careful treatment of the basis of finite elasticity and the transition to the classical case, however, make this a useful book. J. E. Adkins

Proceedings of the International Conference on Nuclidic Masses

McMaster University, Hamilton, September 12–16, 1960. Edited by H. E. Duckworth. Pp. xi + 540. (Toronto: University of Toronto Press; London: Oxford University Press, 1960.) 80s. net.

THE complexities of nuclear structure having as yet defied all efforts at an overall interpretation, it is becoming increasingly recognized that more and more precise data on nuclear properties should be sought to provide clues which may lead us to the fundamental laws. An outstanding contribution to this cause is the present table of nuclidic masses published in 1960; it forms the hub about which revolve the discussions of the conference reported in this volume. For the mass compilation a vast array of data was drawn from mass-spectroscopic experiments as well as from all kinds of nuclear reaction measurements, and from β-decay studies. To users of these mass tables the papers in the first session of the conference afford an interesting opportunity of gaining some insight into the magnitude of the task which the compilers have undertaken. The second session directs attention to some of the physical properties of nuclei which can be derived from mass data, dealing particularly with the nuclear surface, total binding energies, and a shell-model interpretation. The experimentalists then take over with a series of lively discussions covering present-day problems and progress in energy standards and calibrations, the measurement of Q-values for nuclear reactions, including charged-particle, photonuclear, threshold and capture reactions, beta-decay energies and systematics, and finally mass-spectroscopic determinations of atomic masses, together with accounts of recently developed instruments, including a new type of radiofrequency mass spectrometer.

Considerable progress has been made in achieving consistency in the mass data, particularly between the reaction and mass-spectroscopic measurements. There remain, however, a number of discrepancies and gaps, which the contributors discuss, pointing the way to further desirable investigations. Another mass compilation and a similar conference are not anticipated for several years. Meantime this volume is likely to be of considerable use to low-energy nuclear physicists and mass spectroscopists. J. M. Freeman

Organic Chemistry Today

By F. W. Gibbs. (Pelican Book No. A461.) Pp. x + 294. (Harmondsworth, Mddx.: Penguin Books, Ltd., 1961.) 7s. 6d.

SINCE Woehler's synthesis of urea in 1828, staggering advances have been made in theoretical and applied organic chemistry. To-day chemical industries founded on oil, petroleum and other organic raw materials are still springing up in Britain. In his book *Organic Chemistry Today*, Dr. Gibbs attempts to describe some of the more important advances and underline their practical implications and significance.

He begins with a clear outline of the scope of organic chemistry and an introduction to molecular structure which should be familiar to every sixth-form chemistry student. Then, in the remaining eleven chapters, he deals with such topics as: oil and petroleum hydrocarbons, coal and coal chemicals, sugars and polysaccharides, proteins and living matter, food, drugs, dyes and pigments. Wherever possible, each topic is developed against a historical background of key-dates and the names of people most responsible for major advances. Schematic diagrams and charts, and structural formulæ even of the rather complex carotenes, porphyrins and vitamins, are most clearly and simply presented. The comprehensive subject index and the short bibliography with a comment on each book are most helpful.

The introductory chapters and the chapter on coal and coal chemicals should appeal to the layman, but the book as a whole is more likely to appeal to the reader who is able easily to interpret structural formulæ and is familiar with the technical terms of organic chemistry: the synonyms isobutene and isobutylene appear indiscriminately in the text without comment. This book is of considerable value to all students of chemistry at sixth-form level and beyond, and is cheap at the price. It also has something to offer those interested in the influence of chemistry on politics and economics, and vice versa. Michael C. Cox

USER RESEARCH FOR THE NATIONAL REFERENCE LIBRARY FOR SCIENCE AND INVENTION

By Sir FRANK FRANCIS, K.C.B.

Director and Principal Librarian, British Museum, London, W.C.1

AN editorial in *Nature* of July 1, 1961, p. 1, subjected the proposal for "The National Reference Library for Science and Technology" (as it was called) to a searching scrutiny, and voiced the anxiety of scientists that the services available in the new Library should be as complete as possible.

Both the British Museum and the Patent Office, the future and present parent organizations of the new Library respectively, are fully aware of the complexities and of the opportunities which the change-over offers. The librarian of the Patent Office, Miss Maysie Webb, who was referred to in the article, is most concerned of all, since she has the task of running the day-to-day machine while at the same time overhauling it and planning its conversion to new, expanded and, it is hoped, even more efficient uses. The Trustees of the British Museum, who have been charged with the control and the administration of the new Library, look on their task as a great opportunity to provide an exemplary kind of library service for special classes of users.

There are, however, some questions of general importance which should be answered so far as possible before more detailed planning takes place. These concern the nature of the service to be provided by the new Library, and it is felt that detailed research into the use which is made of the present Library is needed to provide the essential basis for this future planning. The free access which has always been permitted in the Patent Office Library has, by its nature, precluded any systematic study being made hitherto, and there are few relevant facts or figures to guide us. Briefly, we need to be told or to be able to deduce: (*a*) the degree of 'professionalism' or system shown by the readers in their use of the library and whether there is a pattern, or patterns, in their approach; (*b*) the tools they use in their approach to the literature; (*c*) whether the present acquisitions policy reflects the needs of present and future users; (*d*) the length of active life of the material in the Library.

Research into these questions has, so far as I am aware, never been undertaken on a large scale in this or in any other library. It has now been made possible for us, however, with funds generously placed at our disposal by the Goldsmiths Company, to put in hand such an organized study, and we intend, with the full agreement of the Patent Office, to employ for one year special staff to study the present usage of the Patent Office Library and to investigate so far as possible its likely future requirements, and thus to secure information on which the services of the new Library can be soundly planned.

It is intended to begin by making a broad survey of the categories into which readers fall and of their use of the library and to go on from there to make a much more detailed survey based on a valid statistical sample.

The programme we have outlined for this purpose is as follows:

(1) *Broad survey*
  Categories of readers
    Their profession (patent agents; information officers; research workers, translators; etc.)
    Their purpose (rigorous subject search; specific documents; inventive novelty; browsing; etc.)

(2) (Based on (1)) What is a valid statistical sample for deeper survey? How best to take it?

(3) *Deep survey*
  (*a*) Frequency of visits; time spent; distance travelled.
  (*b*) Foreign language usage
    Can they read foreign languages? }
    Do they? } which languages?
    Will they later? }
  (*c*) Readers coming to consult specific documents:
    How many did they inspect?
    Categories (that is, books, periodicals, etc.)
    What percentage was not examined and why?
  (*d*) Readers coming to carry out a subject search:
    Which sources did they use?
      Library catalogue
      Library indexes
      Abstracting journals
      Book references
      Journal indexes
      Other
    What did they examine (categories)?
    What percentage was useful?
    What percentage of references was not examined and why (not in library; language difficulty; doubtful subject value)?
  (*e*) Specific items examined (dates and titles)
  (*f*) Use of catalogues:

Author catalogue	How many items were sought? How many were found?
Classified catalogue	Did it lead to useful specific material? Difficulties?
Special indexes	Which was used? Did it lead to useful specific material? Difficulties?

Connected with this research into the use of the present Library and the likely use of the new Library, we propose to investigate the present scheme of classification and to see whether it should be replaced. To do this we expect that existing scientific literature classifications will be critically examined and evaluated in relation to the details we discover about the present use of the Library.

The Trustees of the British Museum have appointed Miss Barbara Kyle to carry out this work, and they plan to appoint, to work with her, a full-time science graduate and to call on the services of statisticians and other specialists as required. With the advice of these specialists it is hoped that questionnaires of the highest degree of practicality and significance can be designed and the results usefully assessed.

The editorial in *Nature*, to which I have already referred, stresses the importance of the co-operation of users in seeing that the needs of the new Library are clearly and continuously presented. We need the co-operation of present and potential users of the Library's services in our inquiry, and it is our earnest hope that they will be willing to respond generously to the calls we shall make on them and on their time.

We shall be glad to hear from any who are interested. Letters should be addressed to me, or to Miss Webb or Miss Kyle at the Patent Office Library, 25 Southampton Buildings, London, W.C.2. It is then hoped to make progress reports on our survey in *Nature* from time to time.

CHONDRULES AND THE ORIGIN OF THE TERRESTRIAL PLANETS

By Dr. JOHN A. WOOD

Smithsonian Astrophysical Observatory, Cambridge, Mass.

IN the past decade, hypotheses to explain the origin of the solar system have been advanced which are consistent with almost all that is known about the nature of the universe and about the behaviour of matter. Postulated *ad hoc* events have been minimized. Perhaps there is reason for believing that the science of solar system cosmogeny is converging on the truth.

The hypotheses (see especially Hoyle[1], Cameron[2]) involve, briefly, gravitational contraction of an interstellar cloud; increasing angular velocity of the contracting mass until it became rotationally unstable and spun off matter at its equator; and finally a magnetic coupling which transferred angular momentum from the remaining contracted mass (Sun) to the spun-off disk or nebula. The latter became, eventually, the planetary system.

Meteoritic studies are expected to help us understand the latter part of this history: the formation of terrestrial planets. I would like to point out an important structural characteristic of meteoritic material which I feel is especially closely related to the astrophysical process of solar system formation.

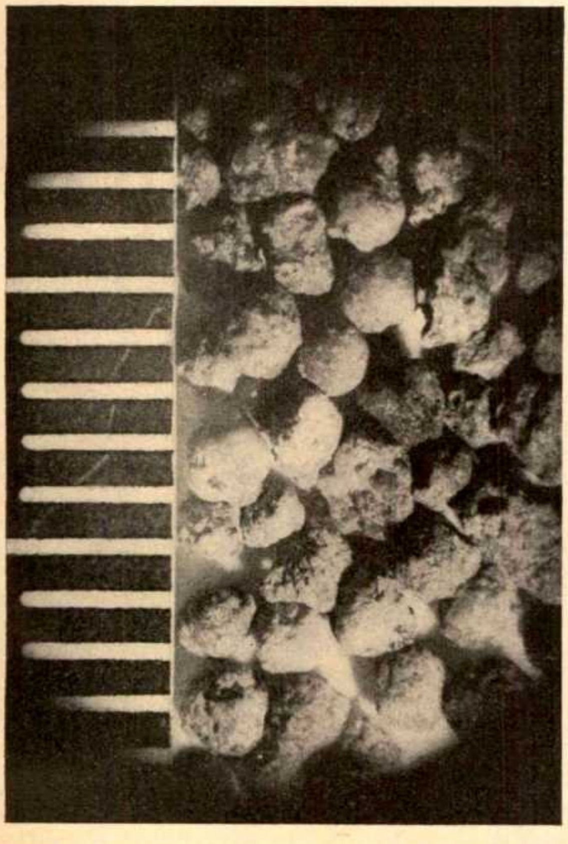

Fig. 1. One particular size fraction (− 10 + 20 sieve meshes) of chondrules separated from the chondrite Bjurböle, with millimetre scale

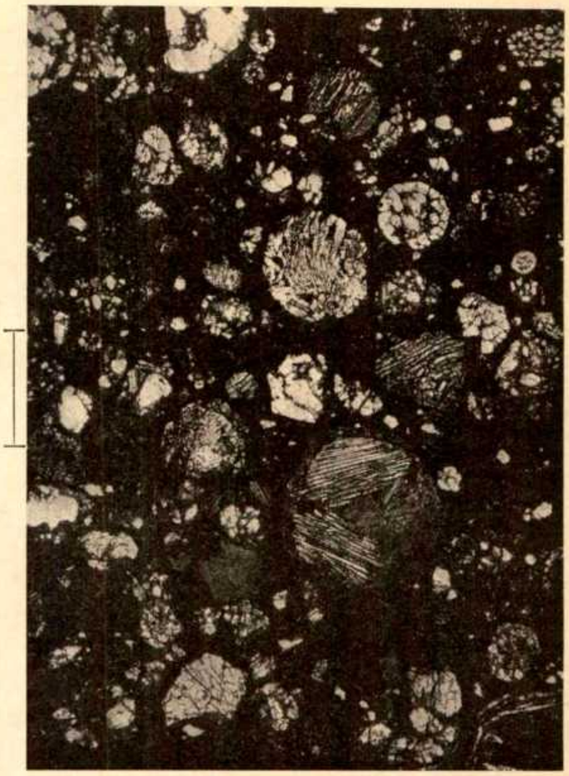

Fig. 2. Thin-section of the chondrite Tieschitz, viewed by transmitted non-polarized light. Length of scale bar, 1 mm. The chondrules (light areas) consist largely of olivine, $(Mg,Fe)_2SiO_4$, and orthopyroxene, $(Mg,Fe)SiO_3$ which are poor in iron. Scattered grains of metallic iron (black) are visible in the chondrules. The opaque (black) matrix in which the chondrules are embedded is a fine-grained ($< 1\mu$) mixture of olivine and Fe_3O_4, with minor amounts of troilite, orthopyroxene and iron metal. Photo. from *Geochimica et Cosmochimica Acta* (ref. 3)

The structures referred to are chondrules. These are solid spheres or spheroids of silicate and metallic minerals (usually mixed), ranging in diameter from 0·5 to 3 mm. (Fig. 1). No terrestrial geological process produces structures which resemble chondrules more than superficially.

Meteorites containing chondrules are called chondrites. Fig. 2 is a thin-section of the chondrite Tieschitz: chondrules make up roughly 50 per cent of its volume; the remaining opaque interstitial material is an extremely fine-grained ($< 1\mu$) mixture of silicates and iron oxide (Fe_3O_4).

Many chondrites contain fewer chondrules; but these have probably suffered re-crystallization which obliterated chondrules during a period of high temperature. Tieschitz and a few other chondrites appear to have been spared this thermal metamorphism[3]. If so, chondrules must earlier have been the dominant structural characteristic of meteoritic material, since 84 per cent of meteorites seen to fall are chondrites. Thus, an understanding of the origin of chondrules probably provides the key to the history of meteorites.

It seems clear that the chondrules were once dispersed molten droplets: their internal textures are igneous in character, and in some cases they contain glass. Not infrequently chondrules are seen which indented one another, apparently while one was still plastic.

I have previously proposed that these droplets condensed from cooling solar gases during the formation of the solar nebula[3,4]. Gases being spun off by a rotationally unstable protosun would have expanded and cooled, and there liquid chondrules might have condensed. Hans Suess[5] earlier suggested that chondrules might be liquid droplets which condensed in cooling gaseous protoplanets, after the hypothesis of Eucken[6].

The observation that chondrule minerals in the apparently unrecrystallized chondrites Tieschitz and Renazzo are unusually poor in iron silicates[3] lends support to this hypothesis: hot solar gases constitute an intensely reducing environment, and all iron condensing and freezing in such an environment must remain in the metallic state[7]. None can enter the silicate melt as iron oxide.

The compatibility of the liquid-droplets concept with the astrophysical framework of Hoyle or Cameron depends on two questions: is it probable that solar gas would cool through the liquid fields of silicates and iron during the contraction and shedding postulated ? If so, could we expect to find the condensation products (chondrules) as far away from the Sun as the asteroid belt (usually held to be the immediate source of the meteorites) ?

The first question requires knowledge of temperatures and pressures in the hypothetical contracting protosun. These cannot be known in detail, but the average temperature and average pressure in a stellar body, as defined by Aller[8], give some measure of what we can expect, and these can be calculated.

$$\bar{T} = \frac{1}{M}\int_0^R T \, \mathrm{d}M_r$$

$$\bar{P} = \frac{1}{M}\int_0^R P \, \mathrm{d}M_r$$

(R is total radius of sphere, M is total mass, M_r is mass beneath radius $= r$).

Aller shows that:

$$\bar{T} = \frac{G(\mu\beta)}{3M\mathcal{R}}\int_0^R \frac{M_r \, \mathrm{d}M_r}{r}$$

and:

$$\bar{P} = \frac{G}{4\pi M}\int_0^R \frac{M_r^2 \, \mathrm{d}M_r}{r^4}$$

independent of mass distribution in the star. The equation for $\bar{T}$ assumes that the ideal gas law holds. ($\mathcal{R}$ is gas constant, G is gravitational constant, μ is average molecular weight of gas, and β is 1 − (radiation pressure/total pressure).)

Assuming radiation pressure can be neglected, $\mu \sim 1$, and $M \sim$ present mass of the Sun, these reduce to:

$$\bar{T}\ (^\circ\mathrm{K.}) \sim 107{,}000\,\frac{d}{R}$$

and:

$$\bar{P}\ (\mathrm{atm.}) \sim 1{\cdot}68\,\frac{c}{R^4}$$

(R in astronomical units), where c and d are functions of mass distribution in the star. These coefficients were calculated for three particular mass distributions, and are presented in Table 1. As the hypothetical protosun contracts, $\bar{T}$ and $\bar{P}$ in the case of model 1 or 3 migrate along *ABCD* in Fig. 3. The temperature–pressure history of model 2 is not significantly different from that of model 1.

Table 1. COEFFICIENTS c AND d FOR THREE STELLAR DENSITY DISTRIBUTIONS

Model		c	d
1. Uniform density	$\rho = A$	0·15	0·20
2. Density varies linearly	$\rho = B\,(1 - r/R)$	0·34	0·25
3. Mass concentrated in centre	$\rho = C \quad (0 \leqslant r \leqslant 0{\cdot}1\,R)$, $\rho = 0 \quad (0{\cdot}1\,R < r \leqslant R)$	1,500	2

The liquid field of meteoritic silicates is approximated in Fig. 3, using the vapour–liquid curve of pure silica in a solar atmosphere (calculated from thermochemical data[7]), and the temperature at which basic igneous rocks begin to melt. The liquid field of iron has been determined experimentally[9]. $\bar{T}$ and $\bar{P}$ in the contracting protosun miss these liquid fields by a substantial margin.

However, Hoyle[1] estimates that the contracting protosun became rotationally unstable at $R \sim 0{\cdot}2$ A.U. and that mass shedding took place at this and lesser radii. In Fig. 3, B corresponds to $R = 0{\cdot}2$ A.U. for model 1 (uniform density) and C to $R = 0{\cdot}2$ A.U. for model 3 (mass concentrated in centre of protosun). The actual density distribution in the protosun probably lay between these extremes. Then, 'average' solar gas spun off at $R \sim 0{\cdot}2$ A.U. or less (that is, closer to D on *ABCD*) and allowed to expand and cool adiabatically or near-adiabatically, would have passed through the liquid field of meteoritic silicates and possibly through the liquid iron field as well. (The lines labelled a in Fig. 3 are adiabats.)

The reader will have mentally objected that matter shed from the surface of the spinning protosun would be at substantially lower temperatures and pressures than the $\bar{T}$ and $\bar{P}$ contemplated. This is so, but as equatorial surface gas was spun off, it must have been replaced by gas from greater depth, which was initially closer to $\bar{T}$ and $\bar{P}$. It is possible that the condensation of chondrules actually occurred within the body of the protosun, as hot gases moving up from depth expanded and cooled. Eventually expulsion of the gas-liquid mixture from the protosun would have accelerated expansion and cooling; this could account for the presence of basic glass in some chondrules, the preservation of which requires very rapid cooling (from 1,200° C. to perhaps 800° C. in a matter of minutes).

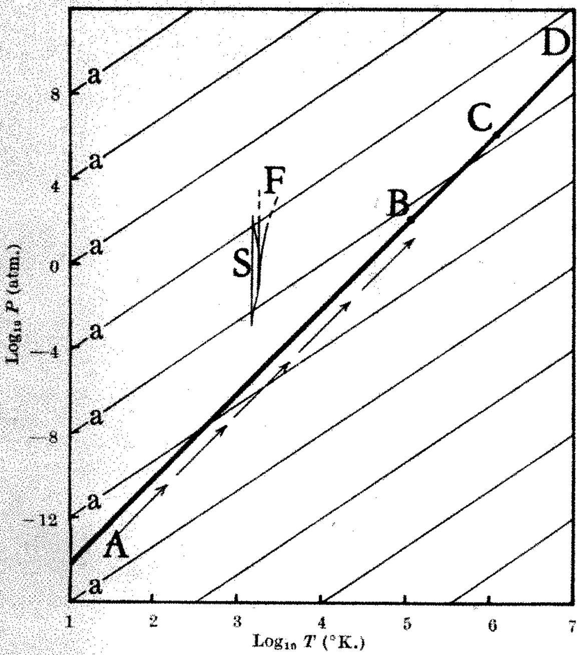

Fig. 3. A temperature-pressure plot, showing the evolutionary path (*ABCD*; arrows indicate direction) of $\bar{T}$ and $\bar{P}$ in a contracting protosun. *B* corresponds to radius = 0·2 A.U. for a protosun of constant density; *C* to the same radius for a protosun with mass concentrated near its centre. Parallel lines (*a*) are adiabats for an ideal monatomic gas, $\gamma = 5/3$. *F*, liquid field of iron; *S*, approximate liquid field of meteoritic silicates

The second pertinent question raised earlier now takes the form: if chondrules could have been manufactured near the protosun's surface when $R \sim 0{\cdot}2$ A.U., how could they have been afterwards transported out as far as the asteroid belt ($R \sim 3$ A.U.)? Hoyle's model provides the appropriate mechanism. Since, while it existed, the spun-off gaseous nebula was constantly being accelerated by the Sun's rotating magnetic field, the velocity of the gas was everywhere slightly in excess of that demanded by a circular Kepler orbit. Hoyle points out that this small excess of velocity would have acted to accelerate orbiting solid particles, moving them farther and farther from the Sun. He demonstrates that particles up to ~100 cm. in diameter would have been so accelerated.

The condensation of liquid silicate and iron droplets is also possible in the astrophysical model of Cameron[2]. This model assumes a much larger initial mass of contracting gas than does Hoyle's, and an earlier onset of rotational instability and mass shedding (at $R \sim 230$ A.U.). Cameron finds that temperatures and pressures which are adiabatically 'upstream' of the liquid fields in Fig. 3 would have prevailed in the interior of the gaseous nebula shed by the contracting protosun, as far out in the nebula as the present asteroid belt. Chondrules would have condensed in gases which convected between the hot interior and cooler surface of the nebula.

If chondrules are indeed surviving condensations dating back to the origin of the solar system, it is not unreasonable to suppose that the whole system of terrestrial planets accreted from 'planetesimals' of this type. Two consequences of such a process are worth developing: one is the opportunity it provides for chemical fractionation among the planets, the other is a possible mechanism of accretion.

It is not possible that all the non-volatile elements and compounds (silicates, iron) contained in the spun-off solar gas condensed into liquids. It is very probable that some or perhaps the great bulk of expanding, cooling solar gas missed the liquid fields delineated in Fig. 3. Certainly condensation continued at temperatures below the melting-range of silicates and the melting point of iron. Much silicate and iron must have condensed directly from vapour to solid, yielding particles of colloidal dimensions: a solid aerosol or smoke. Presumably the fine-grained material occurring between chondrules in Tieschitz was once just such a dispersed aerosol.

Urey[7] has pointed out that when the temperature of such a gas-solid mixture fell to ~ 330° C., the reaction:

$$\mathrm{Fe} + \mathrm{H_2S} \rightarrow \mathrm{FeS} + \mathrm{H_2}$$

would have proceeded until all accessible iron or else virtually all hydrogen sulphide in the system was used up. Any accessible iron remaining would completely react with water vapour when the temperature reached ~ 120° C.:

$$3\mathrm{Fe} + 4\mathrm{H_2O} \rightarrow \mathrm{Fe_3O_4} + 4\mathrm{H_2}$$

We must suppose that $\mathrm{S/Fe} < 1$ in the system, or the chondrites would contain more troilite (FeS) than they do, in place of their substantial content of iron oxide (9–15 per cent by weight FeO). (This supposition is contradicted by recent spectroscopic studies of the solar atmosphere[10], which find $\mathrm{S/Fe} \sim 5{\cdot}4$. However, this value is uncertain; the sulphur spectrum is especially difficult to assess. Also, the compositions of the present solar atmosphere and the primordial nebular gas are not necessarily identical.)

Clearly the colloidal iron 'smoke' particles would have responded immediately to the above reactions as temperature fell; but macroscopic iron grains embedded in the chondrules are shielded from reaction, and would have oxidized only if the chondrules remained in contact with an oxidizing atmosphere for an appropriately long time. (Note that iron grains in museum meteorite specimens, exposed to the Earth's atmosphere for a century or more, are only slightly oxidized.) Hence the use here of the term 'accessible iron'.

Thus, solid particles orbiting in the cooling nebula would have comprised two components: smoke or dust with all iron in the forms FeS and $\mathrm{Fe_3O_4}$, and chondrules containing varying amounts of metallic iron. Obviously the mechanism proposed by Hoyle to move particles outward in the solar system would operate more effectively on dust particles than on chondrules, and more effectively on iron-poor chondrules than on denser iron-rich chondrules. In Hoyle's model, and to a degree in Cameron's model, this fractionating effect could account for the apparent decrease in density of the terrestrial planets with increasing distance from the Sun. It might also explain the existence of two discrete groups of chondrites which differ in both total iron content and degree of oxidation[11].

Cameron's model offers a different fractionating mechanism. Internal pressures in the large gaseous nebula, he pictures, become smaller as greater distances from the centre (Sun) are considered. Note that in Fig. 3, gas cooling through the liquid fields at, say, 10 atm. would pass through liquid iron and liquid silicate fields of similar width; gas at 10^{-1} atm. would pass through a silicate field of substantial width, but liquid iron could condense only over a very narrow temperature-interval; and that from gas at 10^{-3} atm. liquid silicate could condense only over a narrow temperature interval and liquid iron not at all. Non-volatile compounds denied a liquid field, as in the latter instance, would instead condense into colloidal particles. Thus, qualitatively, the nature of the condensate would vary with distance from the Sun just as the planetary densities seem to require: the farther out from the Sun, the more colloidal matter and less chondrules; and the less iron in the chondrules.

For both Cameron's and Hoyle's models, differences in time elapsed before accretion could also have a fractionating effect on particles. Conceivably the Moon accreted at a late date from chondrules which had been exposed to an oxidizing atmosphere so long that they no longer contained metallic iron. Oxidation of all metallic iron in the 'average chondrite'[11] would depress its specific gravity from 3·58 to ~ 3·4, close to the Moon's density of 3·36.

Urey[7] has concluded that planetary accretion cannot have been the result of gravitational attraction alone, but that some "sticking agent" must have been involved. The model discussed in this article provides two possible sticking agents; one is magnetism, since both solid particle components contain ferromagnetic minerals (magnetite in the smoke fraction, iron metal in the chondrules). The other is electrostatic attraction; the enormous surface to volume ratio of the smoke particles would have maximized the effect of charge unbalance, and might have promoted a flocculation or clumping of particles (material between the chondrules in the chondrite Renazzo[3] has a grain size of ~ 200 Å.).

I thank Drs. Edward Anders, A. G. W. Cameron, G. J. F. MacDonald, John Rinehart and F. L. Whipple for discussions and criticisms of the above concepts.

A HYPOTHESIS OF VIRAL PATHOGENESIS

By PROF. CARL C. LINDEGREN

Biological Research Laboratory, Southern Illinois University, Carbondale

Supposedly Genic Nature of Viruses

THE early history of virology was marked with much dispute concerning the question of whether the virus was an autonomous biological structure or merely a by-product of biological activity. D'Herelle[1] stood almost alone, in opposition to Northrup[2], Krueger[3], Bordet[4], and Bronfenbrenner[5], in his insistence that bacteriophage was a living organism.

In the past few decades the pendulum has swung to the opposite extreme, and many have conceived of viruses as the primitive organism which possesses all the basic characteristics of living matter. To many biologists, especially in the Western World, the gene is the fundamental biological unit and, in keeping with this view, viruses have been identified with genes. The virus has been looked upon as a gene, reproducing in the protoplast of its host by virtue of its genic nature. It is often said that the nucleic acid of the virus 'directs' its own replication and nucleic acids have been called 'living' molecules. Although these expressions are obviously objectionable because of their teleological implications, they are interesting since they suggest that the basic concept of viral pathogenesis involves the hypothesis that the virus is a gene operating in the cell by a mechanism indistinguishable from the mechanism of gene-action and diverting the metabolism of the host to its own uses by an active act of enzyme synthesis, rather than by passive growth.

This hypothesis of the 'genic' nature of viruses was the natural outcome of the current conventional view held by many indoctrinated Mendelists that the gene is the only living material and, hence, that only genes are 'self-duplicating'. This extreme view has been intensified rather than diminished by the remarkable and significant discovery that a virus contains a hereditary substance which comprises a molecule of nucleic acid[6]. It has been proposed: (1) that the nucleic acid in the virus is the homologue of a chromosome carrying genes; (2) that since the virus 'chromosome' contains only nucleic acid, genes are composed only of nucleic acid; and, hence, (3) that a knowledge of the structure of the nucleic acid in a virus would be knowledge of the 'structure' of the gene[7]. But, if viruses are non-genic particles, the study of the structure of their 'chromosomes' might not yield any information concerning the structure of the gene. It is the purpose of the present article to suggest: (1) that viruses are non-genic particles; (2) that viral pathogenesis is a process which results from the disruption of the normal mitotic cycle by the presence of the virus. Two basic assumptions of this hypothesis are: (1) that each successive phase of mitosis is initiated by a gene-controlled adaptive enzyme of the host; (2) that the presence of a virus of peculiar conformation may lead to the appropriation by the virus of nucleotides essential to these genes and, by inactivating them 'lock' the cell in a phase of nucleotide synthesis which produces those nucleotides essential to the virus and thus leads to the unrestrained growth of the virus. A subsidiary aspect of this concept is that alteration of other genes may lead to the synthesis of altered enzymes which would synthesize 'new' accessory substances producing protective or invasive envelopes for the viruses.

The hypothesis that the viruses contain genes does not consider the problem of genic balance. When one considers the demonstrated effects of genic imbalance it seems improbable *a priori* that viruses carry genes, since most of the viruses are so very well tolerated by their hosts—a circumstance which would be unexpected if viruses carried active genes.

Pattern-Dependent Heredity

Before considering the virus as a hereditary structure, it will be useful to review the earlier theories of preformation and epigenesis. The preformation theory held that the germ contained the preformed embryo. Early preformationists 'saw' the homunculus in the sperm and conceived of the sperm as a precise duplicate image of the man himself in smaller form. The atomic theory reduced the preformation theory to an absurdity and made the theory of epigenesis, which holds that germs are formed *de novo*, more acceptable to many. There are certain structures under the control of heredity that are obviously epigenetic. An example is supplied by the variety of birds' nests. Some birds make nests by laying twigs one on another, others by weaving threads into a basket and still others by lining dried grass with feathers. Each of the nests is the expression of inherited behaviour; but each nest is built without dependence on a pattern which either resembles the nest or is made of materials similar to, or like those present, in the nest. The possibility exists that many of the structures in the cell are epigenetic to the same degree that a bird's nest is an epigenetic structure.

One might distinguish epigenetic hereditary behaviour from pattern-dependent heredity (since preformation must be rejected *in toto*) by specifying whether the structure supplies the specific pattern for its reconstruction. The prime example of a hereditary structure which supplies the pattern for its own reconstruction on a molecular level is the double-stranded nucleic acid molecule which splits to provide a template capable of attracting the precise complementary components which reproduce the previously existent, double strand. If one describes nucleic acids as pattern-dependent molecules, one might suppose that the chromosome is a pattern-dependent organelle on the following hypothesis: Alexander and Bridges[8] pointed out that a crystal of alum can grow only on a pre-existent crystal which supplies the pattern capable of attracting specific components from the surrounding environment. Their theory is based on the fact that nearly every substance exerts certain residual unsatisfied attractive forces which could function to attract other molecules and, thus, explain how the patterns of a molecule of alum or of a gene may be perpetuated. Their proposal could apply to hereditary organelles which contain deoxyribonucleic acid (DNA) such as chromosomes, or to others such as chloroplasts, mitochondria, cell-walls, membranes, etc., which do not contain DNA. Bungenberg de Jong's[9] theory of coacervation shows by specific examples how the residual attractive forces of molecules can build structures comparable to biological organelles. Bungenberg de Jong's theory (explaining how hydrophilic colloids may become hydrophobic structures) and Alexander's and Bridges's concept of the duplication of a pattern by specifically oriented residual attractive forces are united in the concept of pattern-dependent heredity. Pattern-dependent hereditary structures would supply the patterns for their reconstruction while epigenetic hereditary structures would not. One advantage of this formulation is that it avoids the teleological expression—'self-duplication'.

The *B*-Chromosome of Maize

There are many indications that the inference that the gene is composed only of nucleic acid is unacceptable; the most pertinent example is supplied by the *B*-chromosome of maize[10]. The *B*-chromosome is conventional in appearance and contains nucleic acid distributed like that in normal chromosomes but carries no genes either in the euchromatinic or in the heterochromatinic DNA. It is probably not a maize chromosome but one which drifted into the cell by an illegitimate pollination. Once established in the cell, it continued to duplicate as a chromosome because the cell supplied all the necessary components for its reconstruction as well as the enzymes which reassemble them into the chromosome. The *B*-chromosome, like all chromosomes of higher organisms, is more than a strand of nucleic acid; it contains a great variety of other materials, including at least two kinds of proteins and at least three kinds of nucleic acids—one kind of deoxyribonucleic acid comprising the heterochromatin and another kind making up the euchromatin, as well as ribonucleic acid. The chromosome also contains other conventional localized structures such as the kinetochore and chromomeres. The euchromatinic and heterochromatinic regions of the chromonema of the *B*-chromosome divide synchronously at meiosis and mitosis, but the synchrony of the kinetochore is altered in the conventional way at meiosis. The synaptic behaviour of triploid *B*-chromosomes[11] is identical to the synaptic behaviour of conventional triploid chromosomes and suggests that the chromonema of the *B*-chromosome (and other chromosomes) is asymmetrical in cross-section, as well as along the long axis, since only two chromonemata synapse at any given point while the third chromonema is excluded at that point.

There is a prevailing conviction that the 'fine structure of the gene' may be revealed by genetical and biochemical analysis of the viral nucleic acid, but a complete analysis of the organization of the nucleotides in the euchromatin of the *B*-chromosome could not yield any information concerning the structure of genes.

Genes and Enzymes

Mendel[12] specified that the hereditary particle produced a 'factor' which controlled a 'character', and even Sturtevant[13], who insists that the gene be defined in terms of its location on the chromosome, speaks of 'gene-products' as if the gene were active in the control of a hereditary characteristic. It has been proposed that each gene is associated with a specific enzyme. Hence, the concept of the gene has always embodied the idea of a region of a chromosome active in the production of a 'factor', now generally assumed to be an enzyme.

Replication of Gene-Free Hereditary Structures

Since one must assume that the *B*-chromosome carried genes in the organism from which it was derived, the absence of genes in maize suggests that the active manifestation of a gene requires more than euchromatinic chromosomal DNA to make it operative. It is proposed that the *B*-chromosome, with its gene-less DNA, together with all the other complex components in their characteristic spatial dispositions, is perpetuated passively as a pattern-dependent organelle, the total length being limited by the DNA core. The molecular pattern of the nucleic acid and the organelle pattern of the chromosome together determine the spatial arrangement of the variety of proteins, and other chromosomal constituents in the reconstruction of the chromosome.

The propagation of the *B*-chromosome synchronously with the standard maize chromosomes, suggests the possibility that the prophage[14] may be homologous to the passive *B*-chromosome (rather than to an active chromosome) and that the pattern-dependent prophage may be replicated according to the Watson–Crick hypothesis with the materials and enzymes already available and present in the bacterial cytoplasm as a gene-less fragment of DNA which does not determine directly the composition of any of the bacterial enzymes. On this view, the prophage, the tobacco-mosaic virus[15], the *B*-chromosome and the kappa[16] substance would be examples of genetic, but non-genic, hereditary, DNA-containing structures which are passive in terms of gene action.

This concept is not inconsistent with the idea that the bacteriophage may transmit genes from bacterium to another, if one supposes that the function of the nucleic acid in the chromosome is to provide the base on which genes are arranged[17], rather than being the only component of the gene.

Neither the *B*-chromosome nor the prophage of lysogenic bacteria affects their hosts disastrously because their divisions are synchronized with mitosis, and they draw on the supply of nucleotides only during the phase of mitosis when these materials are being synthesized and are presumably in excess.

Evolution of Mature Infectious Bacteriophage from the Prophage

If prophage is analogous to the *B*-chromosome of maize, one might suppose that the original strands of prophage DNA were incorporated accidentally into bacterial cells and propagated for an indefinite period as relatively harmless parasites. The original accident may have occurred when several different kinds of bacteria were converted to protoplasts together. During the early stages of the evolution of bacteriophage, the newly incorporated DNA segment, the prophage, divided synchronously with the bacterial genome, using the nucleotides and enzymes available during mitosis, and remained without change in the cell during interphase. Unless some direct visual observations were possible this condition would be indistinguishable from direct attachment to the bacterial chromosome. The latter interpretation is at present exploited to explain the phenomenon of one DNA prophage fragment per bacterial nucleus; but it may have less relation to reality than the concept of synchrony.

The first important change in the evolution of the virus occurred when the prophage was altered in a manner which made it possible to multiply out of synchrony with the bacterial genome (vegetative phage). The fact that mature infectious bacteriophage readily reverts to the prophage shows that the restoration of synchrony can be achieved and implies the existence of a mechanism in the cell which makes the chromosomal nucleotides and enzymes available at a specific stage of mitosis. The phenomenon also implies that the cellular mechanism controlling synchrony is stable and difficult to disturb. When prophage first achieved the capacity for unrestricted multiplication, by whatever means, its growth in the bacterial cell led to the destruction of the cell and the release of strands of DNA, but these were not readily infectious, at least for the intact cell. Mutations of the *B*-chromosome which interfered with synchrony would be lethal and escape detection because the *B*-chromosome is transmitted only by cell-division.

The theory that cell division is controlled by the nucleo-cytoplasmic[18] ratio has been invalidated[19] by experimental analysis and a new hypothesis is required. A notable example of nuclear behaviour which is under hereditary (possibly genic) control involves the orientation of the spindles in *Neurospora*. In *N. tetrasperma* the spindles of meiosis are oriented diagonally while in *N. crassa* they are oriented parallel to the long axis of the ascus[20]. In all first generation hybrids the spindles are oriented parallel to the long axis of the ascus, but the genetical analysis of the phenomenon has not been pursued by inbreeding the hybrids. In *Saccharomycodes ludwigii* both types of orientation occur[21,22]. Although no experiments have been made to determine if the spindle orientation is gene-controlled, it seems to be a reasonable hypothesis. It is proposed that the different stages of cell division are under the control of genes which produce adaptive enzymes that successively initiate and terminate the different phases. If this were true, viruses could interfere with the sequence of the phases by the prior appropriation of the nucleotides essential to the construction of the genes controlling the adaptive enzymes responsible for the changes from phase to phase. (This hypothesis accepts the view that DNA is an essential component of a gene; but rejects the view that DNA is the only component.)

The absence of the required nucleotides would destroy the capacity of a host to control mitosis and, hence, disturb the orderly time sequence. The destructive action on the host would have survival value for the virus if it stopped the process at a specific stage in the cycle which limited the metabolism of the bacterium to the construction of those component parts which were essential to the construction of more virus. In *Saccharomyces*[23] homozygous for adenine deficiency an excessively high frequency of apparently non-specific gene-conversion occurs among genes located near each other, as if the deficiency of adenine (an essential component of nucleic acid) led to the abnormal construction of the chromosome with a non-specific effect on all the genes in a given region. (Some genes became unexpectedly normal; others became unexpectedly defective.) In a similar way, the relatively passive action of prior pre-emption of nucleotides essential to a bacterial gene could produce an effect which might appear to be due instead to the active production of new synthetic enzymes by the virus. Since growth occurs in successive cytoplasmic and nuclear phases specific DNA components must be available during nuclear growth and specific RNA components must be available during cytoplasmic growth.

The capacity for massive re-infection through the cell walls did not evolve until a type of virus nucleic acid became available which provided a suitable foundation structure on which other materials in the cells could be coacervated according to a precise and regular pattern. When such a nucleic acid multiplied out of control of the synchrony of mitosis, an epigenetic protein envelope was eventually built on the parasitic nucleic acid which enabled the virus to invade an intact bacterial cell. At this time the cycle of infection and parasitism began and natural selection led to the development of 'improved' parasites in which the accessory substances, coacervated on the nucleic acid DNA base, effected more rapid entry into a wider variety of hosts.

The only hereditary characteristic studied in the bacteriophage is the capacity of the mature virus to penetrate the wall of a bacterium. The capacity for infection is achieved by the arrangement and the specificity of the proteins present in the tail. On this concept, the structure of the mature bacteriophage depends on the maintenance of the nucleotide sequence of the standard wild-type nucleic acid, and (as Benzer's work indicates) almost any alteration of this sequence will lead to the reassembly of a bacteriophage particle without the capacity to reconstitute a virus particle capable of making an infective contact with the wide variety of receptors present in the normal host. But the changes in the sequence of nucleotides in viral nucleic acid which lead to changes in host range specificity are not necessarily comparable with gene mutation, that is, are not necessarily events resulting in a change in the kind or the amount of an enzyme produced by a gene present in the virus itself. The theory suggests that the DNA of the prophage only acts as a base on which the other components of the virus are arranged and that changes in the nucleotide sequence of the virus lead to a non-infective virus because the altered DNA does not form a base on which an effective protein envelope can be assembled.

The proposals concerning bacteriophage apply equally to tobacco mosaic virus; but the latter is transmitted primarily by abrasion and secondarily through the plasmadesmi, and the survival value of the protein which envelops the RNA core arises from the protection which the protein envelope gives the RNA core from the hydrolytic enzymes in the cytoplasm, in contrast to the protein coat of the bacteriophage which acts to effect reinfection of the host.

Does the Bacteriophage Directly Control the Synthesis of Enzyme?

It has been suggested that an analysis of 'mutations' in the bacteriophage may be used as a means of studying the 'fine structure of the gene', and that the gene may be defined in terms of variations in a sequence of the nucleotides present in DNA. During the long sequence of evolution of the *B*-chromosome in maize, many variations in the sequence of the nucleotides in the euchromatin must have occurred. Such changes in the *B*-chromosome are not gene mutations in the conventional sense since they do not result in any change in the synthesis of enzymes, because the *B*-chromosome does not control the synthesis of enzymes. If one called these changes 'mutations' of the *B*-chromosome, they would obviously not be mutations of genes.

The profound disturbances of the metabolism produced by the synthesis of mature infectious bacteriophage within the bacterium may not be the result of enzyme syntheses controlled by bacteriophage DNA but rather the result of some change in the nucleotide sequence of the bacteriophage DNA which leads to the disruption of synchrony due to the development of a greater affinity of the bacteriophage DNA for the available nucleotides in competition with the DNA of the bacterial genome. The mechanism which leads to the reconstitution of a mature bacteriophage particle may result from the selection of a specific bacteriophage DNA with the capacity to cause the disturbances which lead, first, to an alteration in synchrony and, secondly, to the synthesis of components specially adapted to coacervate on the nucleic acid base in such a way that virus particles with the widest possible host range specificity are produced. If the nucleotide sequence of prophage could disrupt synchrony by the prior appropriation of the specific nucleotides essential to the bacterial genome for the control of synchrony, then all the other events of viral pathogenesis, together with a variety of 'new' enzymes[24], could occur in the bacterial cytoplasm due to this basic disturbance in bacterial metabolism, without the nucleotide sequence of the virus having direct control over the synthesis of a single enzyme. The 'new' protein and other components of the viral envelope could result from the distortion of the enzymes previously active in the metabolism of the host by a deficiency of nucleotides essential to the construction of the 'normal' genes. The synthesis of the envelope materials provides an example of epigenetic heredity since the accessory substances do not supply the pattern for their reconstruction.

In present-day biochemical concepts of gene-controlled DNA specific enzyme (or protein) synthesis, it is not assumed that the 'messenger' RNA is derived directly from the chromosomal DNA. Some intermediary mechanism must exist, and I have proposed that this mechanism exists on the chromosome and comprises the gene[25]. The evidence that the prophage is nearly pure DNA would exclude the possibility that the prophage alone possesses the capacity to synthesize the messenger RNA but would not exclude the possibility that the prophage DNA could be replicated through pattern-determined heredity.

This work was supported by research grant *G*-15619 from the National Science Foundation.

KING'S COLLEGE, NEWCASTLE UPON TYNE (UNIVERSITY OF DURHAM)

NEW BUILDING FOR THE PHYSICS DEPARTMENT

By DR. R. ROSCOE

ON March 16 the new building for the Department of Physics of King's College, Newcastle upon Tyne, was opened by Prof. P. M. S. Blackett. A series of lectures were given by other distinguished physicists in order to mark this event, which represents an important stage in the development of teaching and research at Newcastle.

In this Department of Physics, as in many others, work has been carried on for years in an old building, largely designed for other purposes and only partially adaptable to modern requirements. Laboratory work has involved a constant struggle against dirt, bad illumination, poor ventilation, temperature instability, inaccessible servicing and cramped working conditions. In modern laboratories the dust of city air cannot be tolerated: it forms a conducting film on the surfaces of electrical apparatus, it fouls the surfaces of mirrors and the lenses of optical equipment, it makes engraved scales unreadable and plays havoc with the development of photographic plates. A high level of general illumination is necessary, for the inexperienced student is generally unaware that insufficient light is a major cause of inaccuracy in observation and fails to make use of sufficient local illumination. Temperature control is necessary not only for comfort in working but also for the correct functioning of sensitive instruments. But above all other requirements is a degree of flexibility in the arrangement of each laboratory so that it can be adapted to new techniques without recourse to structural alterations or makeshift devices in the years to come. For this reason, fitted furniture has to be reduced to a minimum and services have to be planned so that supplies are available at any reasonable work-place in a re-arranged laboratory. Electrical wiring festooned beneath the ceiling and power points sprouting from the floor are both unsightly and dangerous.

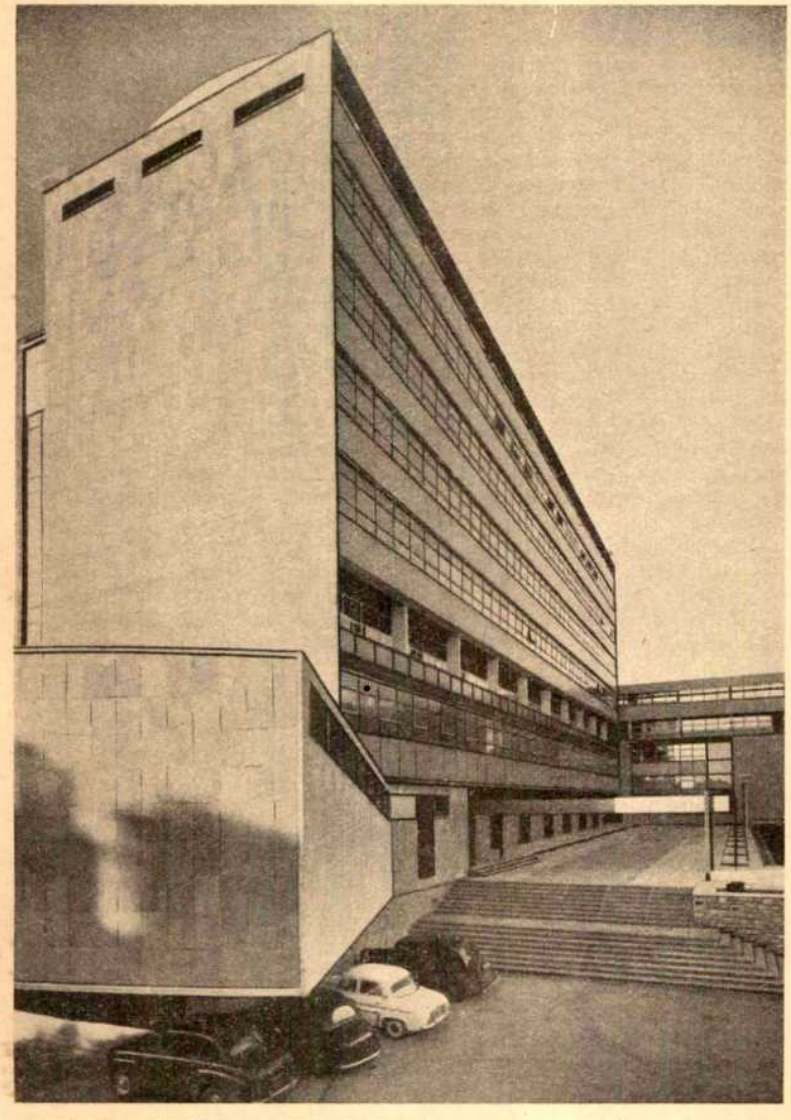

Fig. 1. View of the Teaching Block of the Physics Department, with the Research Block in the background

The architects, Messrs. Basil Spence and Partners, have collaborated closely with Prof. S. K. Runcorn, director of the Department, and his staff in designing the layout and servicing of the new laboratories. Use has been made of the simple principle that if adequate services are available at all points around the walls and the furniture consists of 8-ft. movable benches, placed each with one end abutting on a wall, a large laboratory can be filled with serviced work-places and the necessary circulation space is reduced to a minimum. Electrical supplies are carried in a metal channel with removable side-panels running just above bench-level around each laboratory: a system which has been installed by the architects with satisfactory results in other buildings. Although the main supplies to each room are controlled by master switches at the door, the trunking channel runs through from room to room so that special circuits can be arranged to connect up apparatus in different laboratories without knocking holes in walls or breaking up concrete floors. At present each laboratory is provided with a 240-V. single-phase ring-main with a lavish supply of 13-amp. points. Three-phase points are also fitted, and stabilized supplies of direct and alternating current are available in the Research Block.

The arrangements for supply of water, gas and compressed air also follow a scheme previously used by the architects. The pipe-work is enclosed by removable timber panelling, topped by a shelf 1 ft. wide running along the wall and level with the bench surfaces. The taps are mounted on this shelf, which also provides a useful extension to bench space. It has been found that a single sink is quite sufficient in a large laboratory, but taps and cone wastes must be fitted at regular intervals to provide water for cooling purposes.

The air for the building is filtered and heated before circulation. The main heating, which is thermostatically controlled, is provided by hot-water pipes running beneath the removable panels which form the ceiling. Radiators, which are unsightly and occupy valuable wall space, have been generally eliminated. The problem of providing space for the large horizontal ducts for the distribution of the heating, ventilation and other services over each floor of the teaching block has been overcome in an original manner. These ducts run along the centre-line of the building in the ceilings, the latter being sloped upwards towards the outer walls so as to allow maximum window height. The large area of window space, which contributes much to the interior appearance of the building, is double-glazed in order to reduce heat losses and secure uniformity of temperature. The high level of natural illumination is supplemented in the teaching block by fluorescent lighting. This produces a certain amount of electrical interference which has been reduced to a minimum by the use of tungsten ballast lamps. In the research block, where no interference is allowable, tungsten lighting alone is used.

The research block has presented particular problems of design because of the difficulty in foreseeing future trends of research. A standard laboratory size of 40 ft. × 20 ft. has been adopted, but variety has been achieved by dividing a number of these rooms unequally so as to give laboratories 25 ft. × 20 ft. and 15 ft. × 20 ft. These are all grouped round a central hall, two storeys in height, which can accommodate very large apparatus. Extremely heavy floor loading is allowable here, and a special hard concrete surface is provided which does not produce dust. Floor-ducting of services is necessary in this case as also in the workshops. A helium return system, consisting of a pipe network for the collection of the gas given off by helium cryostats, extends to all laboratories in the research block. A number of rooms has been set aside for special purposes: an X-ray laboratory, a glass-blower's room, a rock-cutting room, an anechoic chamber, a store for radioactive materials and several photographic dark rooms. In order to ensure maximum flexibility, however, an effort has been made to avoid specialization in laboratory design so far as possible.

The building forms a striking addition to the architecture of the University and the City. It demonstrates the possibility of satisfying both practical and æsthetic requirements within the stringent conditions imposed by present-day university finance.

OBITUARY

Dr. A. Muir

Soil science suffered a great loss by the death on February 1 at Harpenden, Hertfordshire, of Alexander Muir, deputy director of Rothamsted Experimental Station and head of the Pedology Department and of the Soil Survey of England and Wales.

Born on September 12, 1906, he was educated at Leith Academy and the University of Edinburgh, where he graduated with first-class honours in chemistry in 1928. As a research scholar he was for a time at the Edinburgh and East of Scotland College of Agriculture before going to the U.S.S.R., where he spent nearly two years at the Dokuchaev Institute of the Academy of Sciences, working with K. K. Gedroiz and B. B. Polynov, two of the most eminent Russian soil scientists. The Russians were pioneers in the infant science of pedology, and Muir was able to study at first hand their work on the soil-absorbing complex, their theories on soil genesis and their genetic system of soil classification which is based on the influence of climate, vegetation, parent material and other factors on the soil 'profile'. He also took part in a soil survey in the Crimea, thereby obtaining experience in the Russian methods of mapping. He made many lasting friendships, and the regard in which he was held by his Russian colleagues is evidenced by the fact that, at their invitation, he revisited the U.S.S.R. on three occasions since the War and was about to go again.

Muir returned home with his valuable Russian experience at a most opportune time. The Macaulay Institute for Soil Research had just been founded, and Muir was one of the small group of able young men who built up the reputation of the new Institute. The Department of Pedology, which he started, was the first in Great Britain, and his early field work developed into the Soil Survey of Scotland.

In 1945, Muir was invited to join the staff at Rothamsted to establish a Pedology Department and the following year he succeeded G. W. Robinson as head of the Soil Survey of England and Wales, the headquarters of which was then transferred to Rothamsted. From small beginnings, he built up the Soil Survey into a very efficient organization which has already mapped 7,500 square miles of England and Wales. He himself devoted much attention to the difficult problems of classification and correlation. At the same time he took a very active part in his Pedology Department, which attracted students from many countries, and he published a number of important papers, the last of which "The Podzol and Podzolic Soils" appeared recently in *Advances in Agronomy*. He became deputy director of Rothamsted in 1956.

Muir was the acknowledged authority on pedology and soil surveying in Britain, and his international reputation led to his advice and assistance being sought in many parts of the world. He became very interested in African soils and personally carried out the soil survey of the Shire Valley project in Nyasaland, publishing papers on this and on soils in Tanganyika. Other activities included an expedition to the Middle East in 1948 to study soils in relation to the corrosion of oil pipe-lines.

His keen interest in geochemistry was probably aroused by translating Polynov's book *The Cycle of Weathering* in 1937. Later, at the Macaulay Institute and at Rothamsted, he became closely associated with V. M. Goldschmidt, who had escaped from the Nazis in Norway and was engaged in writing what is now a standard treatise on geochemistry. Goldschmidt died before it was completed, and it would probably never have been published had not Muir undertaken to complete and edit it. This, in fact, involved compiling the book from Goldschmidt's very incomplete notes.

Muir took a prominent part in re-starting the International Society of Soil Science after the War, and was for a time president of the Commission dealing with Soil Genesis, Classification and Cartography. He gave invaluable help to the Colonial Office, assisting them to establish their Pool of Soil Surveyors based on Rothamsted, and making personal visits to many territories where there were soil problems. For the U.N. Food and Agriculture Organization he undertook many duties and acted as chairman of several of their committees. He renewed his interest in the Middle East as a member of a working party on Land Classification and Soil Surveys and during the past three years attended meetings in Turkey, Iraq and Iran held under the auspices of the Central Treaty Organization. Just before his death he visited India as a member of a Unesco Committee on the establishment of a Central Indian Institute for Pedology and Soil Mechanics.

Muir was a man of great vitality and vigour, equally at home in the field and the laboratory. Always ready to help others, he was held in affection and esteem by his colleagues and staff, and will be greatly missed, both as a scientist and as a man.

He married in 1934 Winifred, daughter of the late Prof. Drummond of the West of Scotland College of Agriculture, and the sympathy of their many friends will be extended to her and her two daughters.

W. G. OGG

NEWS and VIEWS

Henry Dale Research Professorship: Prof. J. L. Gowans

PROF. J. L. GOWANS, Fellow and medical tutor, St. Catherine's College, Oxford, and a member of the external staff of the Medical Research Council at the Sir William Dunn School of Pathology, Oxford, has been appointed by the Council of the Royal Society as its first holder of the Henry Dale Research professorship of the Royal Society. The professorship was established last year following a gift of £100,000 from the trustees of the late Sir Henry Wellcome to the Royal Society. Prof. Gowans will continue his researches in immunology and experimental pathology. He is well known for his solution of the controversial problem of the fate of lymphocytes and his demonstration that the lymphocyte is an immunologically competent cell.

Geology at Manchester: Prof. E. A. Vincent

DR. E. A. VINCENT has recently been appointed to the chair of geology in the University of Manchester in succession to Prof. W. A. Deer, who has transferred to Cambridge (*Nature*, 189, 793; 1961). Dr. Vincent is one of those rare and valuable scientists who belong to two disciplines: in his case, chemistry and geology. In 1936 he went to the University of Reading, intending to be a geologist, but after three years, having taken the general degree course, the War began and he was directed into the school of chemistry. For most of the War years he was an explosives chemist in charge of plant in the Royal Ordnance Factory, Bishopton. He was determined, however, to return to geology, and the acute shortage of geologists after the War gave him his chance. He joined the D'Arcy Exploration Co. as an oil exploration geologist and was concerned with logging the deep boreholes then being put down in the North of England. In 1946 he was appointed to a newly established lectureship in mineralogy and crystallography in the Durham Colleges (University of Durham), where he started a small chemical laboratory for silicate analysis and began his studies in chemical mineralogy, for which he is now so well known. In 1951 he moved to Oxford to continue similar work, first as a University demonstrator, and since 1956 as reader in mineralogy.

Dr. Vincent's research has been firmly based on his chemical analyses of rocks and separated minerals. He has developed modern methods as they became available, and in recent years has pioneered the use in geology of neutron activation and radioactive tracer methods of analysis. His earliest work was on Tertiary dykes, particularly the nature of the residual liquids produced by crystal fractionation, and he has collaborated from the chemical side in the investigation of several other aspects of Tertiary igneous rocks. His detailed studies of the iron–titanium minerals of the Skaergaard igneous complex, by analytical, optical and magnetic methods, have made him an authority on this group of minerals. Another of his interests is the distribution of trace elements, as determined by neutron activation; he has particularly worked on gold, silver, thallium and arsenic in differentiated igneous rocks. While Dr. Vincent's research has been in the field of chemical mineralogy and petrology, he has always retained a great interest in geology as a whole, and all will wish him well in his new sphere as a professor of geology.

U.S. Department of Commerce, National Bureau of Standards: Awards

DR. LEO A. WALL, of the U.S. National Bureau of Standards, has been awarded the Department of Commerce Gold Medal for Exceptional Service. A chemist in the Polymer Structure Section of the Bureau, Dr. Wall was honoured "in recognition of pioneering research in the synthesis of new fluorocarbon compounds for the preparation of organic polymers".

DR. H. W. KOCH, chief of the High Energy Radiation Section of the National Bureau of Standards, has been awarded the U.S. Department of Commerce

Gold Medal for Exceptional Service in recognition of his "outstanding scientific administration, research accomplishments in the field of scintillation spectrometry, high-energy bremsstrahlung spectra and attenuation of high energy radiation".

Silver Medals have been awarded by the U.S. Department of Commerce to the following members of the National Bureau of Standards: R. F. Ackermann, for his work in connexion with the development of high-precision techniques and equipment used for calibration of line standards of unusual length; W. W. Brown, for his part in the establishment of long-wave standard frequency broadcast stations including station *WWVL* at Sunset, Colorado; Dr. L. V. Spencer and C. M. Eisenhauer, who received a joint award for outstanding contributions to civil defence, through the development of radiation shielding engineering; Dr. D. Goodwin, for his work on measurements of the thermodynamic properties of fluid hydrogen; H. W. Lance, for outstanding performance in improvement of electronic standards, measurements and calibrations; C. E. Haven, for his contributions to dimensional metrology and standardization; G. Hefley, for his work in innovating and developing the "Loran-*C* Clock"; M. R. Meyerson, for his contributions to the field of physical metallurgy, particularly with reference to the development of gauge block steel; A. Mijares, for his contribution to the Bureau's technical programme over a long period of time; Dr. R. S. Roth, for contributions to the knowledge of inorganic phase relations in the field of non-metallic mineral products and for active and meritorious authorship; Dr. A. H. Scott, for his services in the field of precision measurements of the dielectric properties of matter; F. Sera, for his achievements in operation and improvement of the continuous broadcast of technical radio services; Dr. M. C. Thompson, for his part in the conducted research on the physics of the troposphere; Dr. W. L. Wiese, for outstanding research in the field of plasma physics.

Britain and the European Markets

UNDER the title *Producing for European Markets*, the text of five papers given at the Joint British Productivity Council–Export Council for Europe conference at the 1961 Factory Equipment Exhibition in London has now been published by the British Productivity Council (Pp. 40. London: British Productivity Council, 1962. 2*s*. 6*d*.). Mr. Bertil Neuman, a marketing consultant of Stockholm, discussing Europe's consumer goods requirements, makes some criticism of British business men, more particularly of lack of sales policy and attention to details of consumers' requirements, and urges the need to look well ahead. Mr. J. Hanning, managing director of a Paris firm, dealing with Europe's capital goods requirements, also insists on the importance of marketing capital goods which represent some technical advance, but his paper is noteworthy for constructive suggestions about the qualifications of agents, specifications, the importance of punctuality and of avoiding the use of abbreviations and ambiguities, etc. The Hon. Brian Rootes, dealing with the way Britain can face the challenge of Europe, is confident that Britain has the technical capacity, but stresses the need for rationalization of products, standardization including the adoption of the metric system of weights and measures, attention to safety and like requirements, and the framing of common policies in testing methods and like matters. The remaining two papers, by Mr. A. S. Booth and Mr. O. F. Reichwald, present case studies of experience with consumer goods and with capital goods, respectively. The former lays stress on packaging, the utilization of spare capacity, increasing the efficiency of production, and the guaranteeing of quality and delivery, while the latter emphasizes the vital importance of attention to detail and of prompt servicing.

Royal Dutch Shell Group : Chemical Enzymology Unit

A CHEMICAL ENZYMOLOGY UNIT, with a new laboratory near Sittingbourne in Kent, is being set up by the Royal Dutch/Shell Group. Jointly in charge of this Unit will be Dr. J. W. Cornforth, for some years a member of the National Institute of Medical Research, and Dr. G. J. Popják, at present director of the Medical Research Council's Experimental Radiopathology Research Unit. They will be assisted by Dr. Rita Cornforth, wife of Dr. John Cornforth. The Unit's work will embrace both basic research and research on topics of shorter-range interest—mainly, but not exclusively, in the sphere of 'biological chemistry', on which science Shell relies very largely in its development of pesticides and herbicides.

The search for new chemicals and their testing for this purpose is already carried out at Woodstock Agricultural Research Centre, near Sittingbourne. Close to it is the Tunstall Toxicology Laboratory. The new Enzymological Laboratory brings into this same area a third focal point—that for basic chemical studies in relation to life processes.

Dr. Popják will join the Unit on October 1 and Dr. and Mrs. Cornforth on November 1. Their laboratory is expected to be completed on April 1, 1963. In addition to the permanent staff, a limited number of scientists working in kindred fields in the universities will be welcome there for periods of research up to about three years in duration.

Register of Research in the Human Sciences, 1960–61

UNDER the heading *Register of Research in the Human Sciences, 1960–61*, the Warren Spring Laboratory of the Department of Scientific and Industrial Research has issued a most useful compendium concerning research bodies within the United Kingdom dealing with the human sciences (Pp. xi+44 (11 plates). London: H.M.S.O., 1962. 10*s*. net). Included within this title of 'human sciences' are such subjects as anatomy, cultural anthropology, industrial relations, management, medical sociology, physiological psychology, physiology, political science, psychology, social disorganization (criminology), social economics, economic history, social psychology, sociology and demography, and various marginal entries. The major section details the various fields of research, giving the address, telephone number and director of the research institutes, councils, laboratories, etc., concerned. Under these are listed the projects which have been or are being undertaken, including a brief description, the name of the person (or research committee) responsible for the research, research workers, approximate dates of starting and completion of interim and final reports, bodies concerned with the inquiry, etc. An index of institutes and their entries, dealing with universities, technical colleges, other institutes and private research workers, is supplied, and also a subject-index. The register is a most useful publication and an essential reference work to those who have to, or wish to, keep track of research in the human sciences, to those who wish to know where the effect of lighting installations and type of street surface visibility is being investigated, where retirement policies for industry are considered, what goes on in the Centre for Urban Studies, or what are the publications on smoking from the Department of Public Health and Social Medicine, Edinburgh, etc.

Films on Natural History Subjects

The Intelligence Unit of the Council for Nature has recently issued a list of 16-mm. films on natural history subjects, Part 1: *The British Isles and Europe*. The list has been prepared for the benefit of natural history societies, teachers and others wishing to prepare programmes and educational courses with a natural history content. Films aimed at very young children are omitted and those for children aged between 9 and 15 are indicated. Films are listed in the general headings of: world of life series, secrets of life series, secrets of nature series; ecological films; films on British regions; Europe; birds; fish, reptiles and amphibians; invertebrates and plants. Part 2 will be prepared during 1962 and will cover the rest of the world. Details are supplied of the distributors, whether the films are sound or silent, or black-and-white or colour, running times and whether or not teachers' notes are supplied. The cost of hiring these films is indicated when necessary. Copies of the list are available from the Council for Nature, 41 Queensgate, London, S.W.7.

County Naturalists' Trusts

The Council of Nature reports that, during 1961, naturalists' trusts have been founded in Glamorgan, Sussex, Hampshire and the Isle of Wight, Devon, Dorset, Suffolk, Gloucestershire and Derbyshire (*News for Naturalists*, 3, No. 2; January 1962). In addition, the West Wales Field Society has decided to turn itself into a naturalists' trust. Plans for trusts are also going forward in Northumberland, Durham and the Lake District, and discussions are taking place in several other countries. All counties south and east of a line drawn along the northern and western borders of Yorkshire, Derbyshire, Staffordshire, Worcestershire, Gloucestershire, Somerset and Devon are now covered by County trusts, except for Northamptonshire, Nottinghamshire, Somerset and Wiltshire.

Project Mohole Exhibition at the Geological Museum

The Project Mohole is featured in a special display at the Geological Museum, Exhibition Road, South Kensington, London, S.W.7. The display provides background information on the American plan to drill through the Earth's crust underlying the ocean to the Mohorovičić discontinuity and to the mantle beneath. The 'Moho' is the level, some 20,000 ft. below the deep ocean floor, at which there is a marked change in the velocity of earthquake waves, and is taken to be the base of the Earth's crust. The project is being carried out for the U.S. National Academy of Sciences National Research Council by the American Miscellaneous Society (see *Nature*, 184, 140; 1959). The central feature of the exhibit is a vertical 25-ft. scale section of the Earth's crust beneath the ocean with a model of the drilling barge and drill-string to the same scale. A cut-away globe summarizes the present state of knowledge of the Earth's interior, and a large coloured diagram shows the constitution of the continental and oceanic areas of the Earth's crust. Details are also given of the methods used in the successful experimental drilling carried out during 1961 in the Pacific Ocean in 11,700 ft. of water. A full-sized model of the diamond-armed drilling bit used in the experimental drilling is accompanied by specimens of the industrial diamonds used in this type of bit. The display will remain on show until the completion of the project, and it is intended to incorporate results as they become available.

The South African Museum

In the annual report of the South African Museum for the period April 1, 1960–March 31, 1961, reference is made to forthcoming building operations which will give additions to the main building and a new administrative block (Pp. vi + 34. Cape Town: South African Museum, 1961). In view of the restoration of the old Supreme Court to house the Cultural History Museum, it is suggested that it is linked with Koopmans de Wet House to form a separate entity with its own Board of Trustees and Director. With the aid of a trawler, the marine biologists at the Museum were able to obtain some valuable results in their research on tunny biology. Other research projects include serial sectioning of the skulls of many Deinocephalia and the Middle Triassic dinosaurs and advanced mammal-like reptiles. A large diorama depicting the bird life of Malgas Island, and exhibition on Bushman music and "Cape Town 1910–1960" have been completed during the year. As with so many recent reports on museum work, the format of cover, printing and illustrations are modern and attractive.

Computer Methods, Machines and Services

The proceedings of the sixth congress on theoretical and applied mechanics, held at Delhi in December 1960, have just appeared in print (Pp. xi + 316. Kharagpur: Indian Society of Theoretical and Applied Mechanics, Indian Institute of Technology). The papers range from mathematical analyses of magneto-hydrodynamic shock-waves to practical studies of flange connexion design for pressure vessels. An addendum contains material on a symposium entitled "High-speed Computation Methods and Machines" that was included in the programme of the meeting; it dealt with both analogue and digital computation, and gives a picture of some of the computing resources available in India. The January issue (Nos. 15–16, October 1961–January 1962) of the *Bulletin of the Provisional International Computation Centre*, Rome, contains interesting papers on machine translation and on learning machines. The *Bulletin*, of which this is the fifteenth issue, performs a useful service in documenting European computer activities and in providing detailed information on the facilities available in the various laboratories.

Age of Leads in Britain

Recent work on the abundance of lead isotopes in British galenas suggests the existence of at least six distinct periods of mineralization. These were: Caledonian, probably mainly of Middle and Upper Silurian age; Devonian; Lower or Middle Carboniferous; Hercynian, probably Lower Permian; Mesozoic, probably Upper Triassic; Upper Mesozoic, probably Upper Jurassic or Cretaceous. It is interesting to find that there is no isotopic evidence for Tertiary sulphide mineralization within the British

Isles. These conclusions follow from determinations of lead isotope abundances of 98 galena specimens from Great Britain and Ireland, the ages being calculated using the Holmes–Houtermans model (*Philosophical Transactions of the Royal Society of London.* Series A: Mathematical and Physical Sciences. *Lead Isotope Abundance Studies on Mineral Occurrences in the British Isles and their Geological Significance.* By S. Moorbath. Pp. 295–360. London: Royal Society. 21*s*.). These model ages show good agreement with published values of the absolute ages of genetically associated igneous rocks. Since most British galenas are vein-type deposits of epigenetic type which have traversed sedimentary and igneous rocks, this agreement suggests that the assumptions of the Holmes–Houtermans model do not contradict the hypothesis of a crustal rather than a mantle origin for lead ores. This view is in harmony with one of an early differentiation of the Earth's crust and repeated rejuvenation of ancient fold belts, rather than with one of continual continental accretion around marginal mobile belts.

Forest Research in Sweden

THE recent volume of reports from the Forest Research Institute of Sweden is devoted to a variety of subjects, and Scots pine is prominent among them (*Meddelanden från Statens Skogsforskningsinstitut,* Band 49, 1960–1961. *Reports of the Forest Research Institute of Sweden,* Vol. 49. Pp. iv+580. Stockholm: Statens Skogsforskningsinstitut, 1961). It has been found that mortality among pine seedlings caused by parasitic fungi can be prevented by pre-sowing treatment of the soil with methyl bromide. Storage of pine pollen is best done at very low temperatures (–18° C.) if the fertilization capability is to be preserved. Although there is nothing surprising in the conclusion reached that heavy low thinnings for Scots pine are economically and biologically superior to heavy crown thinnings, this is supported by a description and analysis of thinning experiments over a period of 54 years. A very good article on the sawfly, *Diprion* (*Microdiprion*) *pallipes* Fall., is well illustrated and includes an excellent colour plate. Another article on forest entomology is concerned with the larch shoot moth, *Argyresthia laevigatella* H.S. The reports are attractively presented and well supported with references. Four reports are in English, and of the remaining six there are English summaries for four and German summaries for two—those on forest entomology.

Indian Forest and Forest Products Terminology

PART 1 of a publication recently issued as an *Indian Forest Record,* entitled *Indian Forest and Forest Products Terminology,* deals with the general subject of forests (Vol. 10, No. 6. Pp. iv+125–215. Delhi: Manager of Publications, 1961. Rs. 6.00 nP., 9*s*. 6*d*.). This is a glossary of some 2,000 terms used in sylviculture, protection, mensuration, management, ecology, soil science and allied subjects. Most of them have been taken from the *British Commonwealth Forest Terminology,* while others have been gleaned from other well-known appropriate glossaries, and there are a few terms which are particular to India. The terms included in this glossary are comprehensive and correct, but 'assortment table' is perhaps too narrowly defined. It can be argued that 'crop' is used in an unfortunate sense at times, but this is a common failing nowadays when the growing of trees is too much likened to an agricultural crop. On the other hand, the correct 'to bark' is insisted on and improper 'to debark' is, according to the glossary, to be deprecated. Three appendixes provide classifications of the principal sylvicultural systems, trees by crown classes and thinning densities. This glossary is obviously intended for use in India and there it will be welcomed; it is a pity that a more convenient format and hard covers had not been provided. Part 2, dealing with forest products, will be published at a later date.

Gerontology and Geriatrics in the U.S.S.R.

SOME of the present-day developments in gerontology and geriatrics in Russia were discussed at a conference in Moscow during 1960. A brochure issued by the Division of General Medical Sciences, Center for Aging Research of the U.S. Department of Health, Education and Welfare, provides a translation of all the papers in summary form (Public Health Service Publication No. 884. Pp. viii+81. Washington, D.C.: Government Printing Office, 1961. 35 cents). These range from activities of the Republic Gerontological Society of the Kazakh S.S.R.; structural aspects of ageing; psychiatry of old age as an independent branch of psychiatry; organization and methods of conducting group physical culture activities among middle-aged and elderly persons; the effect of physical exercise on the cardiovascular system of elderly persons; the causes of death among elderly persons in one region of an industrial city of Zazakhstan; senile dementia; features of cataract surgery on persons 80–118 years of age; treatment of certain diseases of elderly persons with a 2 per cent solution of novocaine; the work capacity of persons with cerebral atherosclerosis; and premature senility and the treatment of cerebral artherosclerosis.

The Origin of Life

THE latest version of A. I. Oparin's hypothesis of the origin of life on the Earth is given by its author in a short article (*Priroda,* 7, 5; 1961). The story begins with an abiogenic generation of amino-acids in the primitive atmosphere, their gradual synthesis into proteins and the eventual formation of the 'primitive broth', composed of polymolecular 'concervate' drops, which eventually give rise to bacteria and blue-green algae. Future aeronauts may discover life existing on other planets, and carbon meteorites suggest the possibility of such an occurrence. Wider concepts of the probability of life in the cosmos, the progress of evolution and the future of mankind are discussed elsewhere by A. I. Baumstein (*Priroda,* 12, 76; 1961).

International Geological Congress:
Twenty-second Session

THE twenty-second session of the International Geological Congress will be held in New Delhi during December 14–22, 1964. The following subjects have been provisionally selected for discussion, each subject corresponding to a section of the Congress: (1) geology of petroleum; (2) geological results of applied geophysics; (3) Cretaceous–Tertiary boundary including volcanic activity; (4) rock deformation and tectonics; (5) genetic problems of ores; (6) minerals and genesis of pegmatites; (7) plateau basalts; (8) Tertiary mammals; (9) Gondwanas; (10) Archæan and Pre-Cambrian geology; (11) Himalayan and alpine orogeny; (12) isostasy; (13) charnockites; (14) laterite; (15) sedimentary geology and sedimentation; (16) other subjects. The programme will also include excursions. Copies of the first circular are obtainable from the Assistant Secretary, Royal Society, Burlington House, London, W.1, or direct from the Secretary General, Twenty-second Session, International Geological Congress, Geological Survey of India, 27 Chowringhee, Calcutta 13.

Carlsberg–Wellcome Travelling Research Fellowships, 1962–63

APPLICATIONS are invited for the Carlsberg–Wellcome travelling research fellowships, 1962–63, the object of which is to encourage co-operation, on an exchange basis, between Danish and British research workers in any branch of the natural sciences which has a bearing on human and animal medicine. One fellowship annually is awarded to a candidate from the United Kingdom for a year's work in Denmark and one annually to a Danish candidate for a year's work in the United Kingdom. The stipend may range from £1,000 to £2,000 per annum (or the equivalent sums in Danish kroner), travelling and some incidental expenses being provided in addition. Further information can be obtained from the Assistant Scientific Secretary of the Wellcome Trust, 52 Queen Anne Street, London, W.1. Applications must be submitted before April 19.

Wellcome–Swedish Exchange Research Fellowships in Medical Science, 1962–63

APPLICATIONS are invited for the newly created Wellcome–Swedish travelling research fellowships, the object of which is to encourage co-operation, on an exchange basis, between Swedish and British research workers in any branch of the natural sciences which has a bearing on human and animal medicine. One fellowship annually is awarded to a candidate from the United Kingdom for a year's work in Sweden and one annually to a Swedish candidate for a year's work in the United Kingdom. The stipend may range from £1,000 to £2,000 per annum (or the equivalent sums in Swedish kroner), travelling and some incidental expenses being provided in addition. Further information can be obtained from the Assistant Scientific Secretary of the Wellcome Trust, 52 Queen Anne Street, London, W.1. Applications must be submitted before April 19.

University News: London

TITLES have been conferred on the following in respect of their posts at Birkbeck College: professor of mathematics, on Dr. C. H. Dowker; professor of experimental physics, on Dr. W. Ehrenberg; professor of electrochemistry, on Dr. D. J. G. Ives; reader in mathematics, on Dr. Paul Vermes. The title of professor of anatomy has been conferred on Dr. A. D. Morgan, in respect of his post at Westminster Medical School.

California, Berkeley

THE building housing the new Department of Nutritional Sciences on the Berkeley campus of the University of California has been named the Agnes Fay Morgan Hall in honour of Prof. Agnes F. Morgan, emeritus professor of nutrition and chairman of the Department of Home Economics during 1918–54. Prof. Morgan, well known for her work in nutritional science, also holds the Garvan Medal in chemistry, the Borden Award in nutrition, and is a fellow of the American Institute of Nutrition.

Announcements

DR. CHARLES H. TOWNES, provost of the Massachusetts Institute of Technology, formerly professor of physics in Columbia University, New York, has been awarded the John J. Carty Medal of the U.S. National Academy of Sciences, in recognition of his pioneering work in the development of the maser (microwave amplification by stimulated emission of radiation).

DR. MONROE EDWARD SPAGHT, president of the Shell Oil Co. in the United States and a director of the American Petroleum Institute, has been appointed president of the Society of Chemical Industry (U.K.) for the year 1962–63. He has been a member of the Society since 1950 and was chairman of the American Section during 1956–57.

A SEMINAR on "Physics and Computers", arranged by the American Institute of Physics, will be held in New York City on May 22. Further information can be obtained from the American Institute of Physics, 335 East 45 Street, New York 17.

THE spring conference of the British Association for Commercial and Industrial Education on "Industrial Training—Whose Responsibility ?" will be held in London on May 10. Further information can be obtained from the Conference Secretary, British Association for Commercial and Industrial Education, 26A Buckingham Palace Road, London, S.W.1.

THE third general meeting of the International Mineralogical Association, sponsored by the Mineralogical Society of America, will be held in Washington, D.C., during April 17–20. In addition to business meetings and a session devoted to a general selection of papers, there will be two symposia on "Layered Intrusions" and on "The Mineralogy of Sulphides". Further information can be obtained from Alvin Van Valkinburg, National Bureau of Standards, Washington 25, D.C.

A CONFERENCE on "The Design of Talking and Writing Machines for the Rehabilitation of Communication Disabilities", organized by the Foundation for Medical Technology in conjunction with the Institute of Physical Medicine and Rehabilitation, will be held at the Institute of Physical Medicine and Rehabilitation, New York, on May 16. Further information can be obtained from Mr. C. Berkley, Foundation for Medical Technology, 2 East 63rd Street, New York, 21, N.Y.

AN international symposium on "Organic Chemistry applied to the Study of the Natural Products excluding Steroids and Polypeptides", to commemorate the seventy-fifth anniversary of the foundation of the Société Chimique de Belgique, organized by the Société under the auspices of the International Union of Pure and Applied Chemistry, will be held in Brussels during June 11–14. The symposium will be divided into five sections: structure of new natural products; methods used for the determination of chemical structures; syntheses and chemical reactions; biosynthetic theories; mode of action of naturally occuring compounds in biological processes. Further information can be obtained from the secretary of the symposium, Dr. F. Martin, 68 rue Berkendael, Brussels 6.

ERRATUM. In the heading of Table 1 of the communication "Gastric Esterases of Pigs", by R. A. Evans and D. A. Stansfield (*Nature*, 190, 1110; 1961), the words "of Triacetin" should be omitted.

AN INTERNATIONAL COMPARISON OF SCIENCE EDUCATION

MR. J. L. LEWIS, senior science master at Malvern College, has examined methods of teaching science in the United States, Western Germany and the U.S.S.R. In the first of two articles, he compares the relative merits of those methods with such as are used in English schools (*Esso Magazine*, Winter, 1961/1962).

Education in the U.S.S.R. is compulsory during the ages of 7–18 and the same course is followed by every child for the first eight years of his or her time at school. This basic course starts with the Russian language, Russian literature and mathematics. At the age of nine a foreign language is introduced, then history, geography, Leninism–Marxism theory and biology. A little later physics is begun and, a year later, chemistry. In other words, the Russian educational curriculum is fairly broad and the same standard, equivalent to the General Certificate of Education in England, is attained by every child. There is no streaming and no examination at 11-plus.

Mr. Lewis claims that pupils in Russian schools believe passionately in work. It is even a privilege, not a punishment, to be kept in after school. Education is the one way to open up the future for the Russian boy or girl, the one way to enable them to avoid spending their lives in factory or in field. That is an inducement. There is also the passion for the acquisition of knowledge which is too frequently lacking in English schools. Mr. Lewis includes in his picture of Russian life street corners abounding in bookstalls filled with books on physics, mathematics and astronomy. Throughout the day trestle tables are erected and crowds collect around their array of books. In the Moscow Metro and in the buses people are reading books on physics, mathematics and astronomy. Education in physics really matters. He rightly or wrongly questions whether it really does matter in Britain.

Western Germany has long had its tradition of good physics teaching. Physics is respected as a subject of major importance for the second half of the twentieth century and plays its part in the education of every boy and girl in the German *gymnasiums*. Could this be claimed for English grammar schools, where the educational system is still fundamentally classical in tradition? Latin, from the age of eight to sixteen, for several periods a week is said to provide "a broad liberal education". Two periods a week of science at the age of eleven have been called "gross specialization". It would seem that the English people are too complacent when others are believing passionately in the slogans "Work, work and work" and "Physics is life".

Other dangers, Lewis believes, also beset us. Teachers often tend to teach what they themselves were taught. This has doubtless contributed to the surprisingly few changes in the content of the school science courses despite advances which have been made. Physics has remained in its watertight compartments—heat, light and sound; magnetism and electricity. There seems to be an unawareness that there is any modern physics of relevance to the schoolboy or girl. There are, of course, still those who say that all modern physics should be left to the universities, but they forget how small is the proportion of those at school who will study physics at the university. In the second half of the twentieth century every boy and girl leaving school ought to have some knowledge of radioactivity and X-rays. The new syllabuses recently proposed by the Science Masters' Association have included some of this: however, the tragedy is that it has taken sixty years to begin to get topics included despite the fact that the U.S.S.R. and Germany have taught modern physics in schools for many years. Mr. Lewis rightly poses two questions which lead from such developments. What of equipment in English schools? What of laboratories? On the whole there is no great problem in England with regard to laboratories; however, with equipment, the situation is not satisfactory.

Throughout Western Germany there is an immense wealth of large-scale demonstration equipment for the teaching of science. University lectures are always accompanied by demonstrations which naturally stimulate and maintain the interest of the student. How often in England does the student in the university or the pupil at school have to be content with talk and chalk and occasionally the lantern slide. How easy it would be to capture the imagination of the boy with some of the excellent equipment available in Germany.

Good demonstration equipment is expensive. But in Germany, after the Second World War, it was decided that modern physics should be taught in German schools. To make this possible the Federal Ministry of Atomic Energy prepared a plan to make available 18 million D.-marks (just less than £2,000,000) and the funds were distributed at the rate of 12,000 D.-marks or more than £1,000 per school. This was given equally to State schools, municipal schools and to private schools, on condition that it was to be used on equipment for developing the teaching of modern physics in the last three years in the *gymnasium*. This special grant transformed the teaching, and it accounts for the expensive demonstration equipment used. Mr. Lewis warns that, despite the efforts now being made, England, and Britain as a whole, is in great danger of lagging behind.

Mr. Lewis now comes to the question of the teachers and whether or not, in England, the best use is made of the material available.

The English science teacher, in general, is given complete freedom to present his subject as he wishes. This will lead to the best results if the teacher is good and if he has sufficient time to think out his presentation. The trouble is that there are never enough good teachers and these seldom have sufficient time. The problem is also very real in the U.S.S.R., where it is conceivable that there will never be enough teachers, and consequently they have set about providing the material to enable indifferent teachers to teach well. The Russian science teachers are teaching as much science in less time than their British counterparts due to the fact that the teacher is given more guidance and far more aids to teaching. If the means of teaching science subjects more efficiently were available, the English schoolmaster might achieve much more in fewer periods and the shortage of teachers might not be so acute.

In the U.S.S.R. there are research institutes for devising school experiments and designing apparatus. In England this is usually done by the busy schoolmaster in any spare moments he may have, and, as Mr. Lewis states, "We cannot afford to continue in this amateurish way". Not only is the Russian teacher provided with a complete set of demonstration apparatus for his course, but he is well supplied with films on the subjects being taught. All this does much to help the teacher: it does not impede the good teacher from developing his own ideas, but it does enable the indifferent teacher to achieve a minimum standard, to teach with a minimum of efficiency.

Another serious problem is that, in England, the assumption is made that a young man merely has to take his science degree and can then teach for the next thirty years without ever returning for further instruction, refreshment or guidance. In the United States last year more than 17,000 high school science teachers attended summer institutes. In England, less than a hundred attended Ministry of Education courses for grammar school science teachers. The American summer institutes last from six to eight weeks; the courses in Britain usually last less than a fortnight.

Mr. Lewis has dealt with some of the problems confronting science education in England to-day. They are serious indeed if England, and Britain as a whole, is not to lag far behind what is being done in other countries.

EXPERIMENT IN EXAMINING FIRST-YEAR CHEMISTRY STUDENTS

In teaching chemistry, as with other scientific disciplines, there is a number of objectives. More often than not these objectives remain implicit in the minds of the lecturers. If they are made more explicit, it is usually in rather inexact and personal terms.

A general taxonomy of educational objectives has been developed by B. S. Bloom and others at the University of Chicago which contains six major classes: (1) knowledge; (2) comprehension; (3) application; (4) analysis; (5) synthesis; (6) evaluation. These six classes are subdivided, defined and illustrated by example. Several members of the University of Melbourne Chemistry Department explored the adequacy of this taxonomy for chemistry applying it to old examination papers, and the following simplification of Bloom's definitions of classes was produced:

(1) *Knowledge*, involves simply the recall of material directly taught.

(2) *Comprehension*, involves understanding of the material taught, to the extent that it is recognized when presented in any form.

(3) *Application*, involves the use of such material in a new situation.

(4) *Analysis*, where the breakdown into detail involves both the facts and their relation in a new situation.

(5) *Synthesis*, where previously presented material is assembled to create something new.

(6) *Evaluation*, involves judgments using undefined criteria about values in a chemical situation.

These categories, so defined, were found to cover most questions on a number of examination papers, although one question would often involve the components of several classes.

With this experience as a basis, a first-year paper was set covering all six classes. The questions were so designed that the percentage marks obtained for each class were easily extracted from the total, in the course of normal marking procedure. The examination was taken by 150 students, and as all the questions set were compulsory, the performances were directly comparable. The results have been described by P. J. Fensham of the University of Melbourne (*Vestes*, 4, No. 4; December 1961).

The customary way of assessing performance was in terms of the total percentage for the whole paper. This method gave the following results: honours (1st, 2nd and 3rd combined), 25; pass, 93; fail, 32. These three grades were then analysed by performance in the various classifications, particular attention being directed to the difference between honours and pass, and between pass and fail. It was clear that the major factor distinguishing between honours and pass was better performance of the honours group in classes 1, 2 and 3. This group averaged 78 per cent in the first three classes and 70 per cent for the last three, whereas pass students averaged 54 per cent in both sets of classes. However, twelve students who were graded as pass students achieved at least 66 per cent in classes 4, 5 and 6, whereas eight of the students who were awarded honours all scored less than this for those same classes.

A reasonable hypothesis for this type of examination might be that honours should be awarded to those who perform better at the more complex objectives of the last three classes, assuming a certain competence in the first three. If so, the experiment suggests that the traditional grading by overall percentages involves serious errors in distinguishing between honours and pass students. (A single paper of this type, however, appears unsuitable to make the distinction, for 70 per cent of it had to be devoted to questions in the first three classes, if the material of the course had to be reasonably covered. This meant there was not enough room left in the paper for a sufficient number of questions of classes 4, 5 and 6.)

So far as the distinction between pass and fail is concerned, it might be reasonable to award a pass for a minimum level of performance in the first three classes, ignoring performance in the other classes for this purpose. The results showed that all pass and honours students obtained at least 40 per cent in classes 1, 2 and 3, whereas none of the failed students scored more than 40 per cent in these classes. Thus there was no difference in the result—so far as pass and fail were concerned—using this assessment based on the classification as compared with the overall percentage method. There was, however, a considerable difference in the number of honours grades awarded, for different taxonomic gradings, one of which is as follows:

	Honours	Pass	Fail
Overall percentage grading	25	93	82
Taxonomic grading	40	78	82

The conclusion appears to be that considerable care is needed, particularly at the upper end of the scale, if examining is to provide an accurate assessment of what is sought from students.

SALARIES OF UNIVERSITY TEACHING STAFFS IN BRITAIN

IN a written answer in the House of Commons on March 14, the Chief Secretary to the Treasury, Mr. H. Brooke, stated that the Government had considered the recommendations of the University Grants Committee for recurrent grants for the five-year period 1962–67. It had also considered substantial increases in the salaries of university teaching staffs with the determination to effect the most rapid development of higher education that is consistent with other claims on the nation's prospective economic resources in the next five years and with the Government's policy for incomes. These considerations had made it necessary to depart from the Committee's recommendations and he had informed the Committee that, subject to annual approval of the Estimates by Parliament in the normal way, it should plan on the basis of the following recurrent grants from August 1 next: 1962–63 £56 million; 1963–64, £60·5 million; 1964–65, £65·5 million; 1965–66, £70·5 million; 1966–67, £76·5 million. The grant for the present university year is £49·5 million. These figures exclude provision for rates, which will be financed by special grants outside the quinquennial settlement, and the cost for the universities of the Government's recent request for an increase in the intake of medical students had yet to be finally settled and would also be additional to these figures.

Mr. Brooke reaffirmed the undertakings given last year on the rapidly increasing provision for non-recurrent grants and added that the awards to university students from public funds was also continually growing. In sum, the aggregate cost of the universities to public funds had increased from £50 million to £104 million during the past five years and might increase by at least £50 million in the next five years.

The universities' estimates, including those of the seven new universities authorized during the present quinquennium, indicated that, given adequate financial support, they would be prepared to work to an expansion of the total student population from about 111,000 in 1961–62 to about 150,000 in 1966–67. Mr. Brooke had asked the University Grants Committee to inform the universities that it was the Government's wish that the additional funds should be applied so far as possible to achieving the figure of 150,000. The Government's aim was to continue the expansion to about 170,000 places by 1973–74. These recurrent grant figures are based on rates of academic salaries which came into effect in January 1960. The Government had taken carefully into account the strong arguments advanced by the University Grants Committee for a substantial increase in these salaries, along with the need to expand the teaching staff in relation to the increase in student numbers, but did not feel able to authorize an increase of more than 3 per cent in the bill for academic salaries. Scales based on an aggregate increase of this order would be authorized from April 1, 1962, and would cost about £1 million extra in the first full year. The scales would be reviewed afresh next year. Provision for university expansion was only part of the resources that the Government was devoting, on an increasing scale, to higher education; and all these programmes might need to be re-examined in two or three years' time in the light of the report of the Robbins' Committee on Higher Education. The Government's proposals for the first year of the new quinquennium and for the increase in salaries would necessitate a supplementary estimate of some £4·5 million for 1962–63.

RHEOLOGY OF CLAY SOILS

AT the meeting of the Cambridge Rheology Club held on February 5, Mr. W. J. Thompson (Department of Engineering, University of Cambridge) spoke on the "Rheology of Clay Soils". He pointed out that it is current practice in soil mechanics to use the triaxial apparatus to study the shear characteristics of a soil. In this apparatus a cylindrical sample of soil can be subjected to any desired combination of axial and hydrostatic stresses, the sample being either allowed to drain during the deformation process (drained test) or be maintained at a constant volume (undrained test). The allowable shear strength value used in soil mechanics computations is taken as some proportion of the maximum shear stress τ_m obtained in a constant axial strain-rate triaxial test, although corresponding tests with constant axial stress have indicated that for stresses $> 0{\cdot}8\ \tau_m$ a state of structural disintegration is obtained. Consideration should therefore be given only to the region of the stress-range ($< 0{\cdot}8\ \tau_m$) within which the soil would behave in the field. Present shear theories are generally based on the results of constant strain-rate tests and neglect time considerations.

The existence of a yield-point in the shear deformation of clays, as investigated by Bingham and Scott

Blair, is not generally accepted. Tests by Gueze and Tan with a torsion plastometer, and by Haefeli, have indicated the existence of yield-point and at higher stresses a pronounced tendency for the development of a state of structural disintegration as in triaxial tests. It is considered by several workers that the apparent yield-point is due to measurement inaccuracies and that the true flow-curve is of the thinning thixotropic form observed by Ostwald. Experimental evidence appears to confirm the conclusion reached by Reiner that volume deformation is generally a combination of elastic, viscous and plastic processes. The rate of the water expulsion occurring with volume decrease in saturated soils is governed by Darcy's law.

The large strain behaviour associated with shear-failure may be considered as of an essentially plastic nature, this being generally assumed in the determination of allowable footing loads which correspond to much smaller strains. Simple viscoelastic models are proposed for small strain volume change and shear deformation caused by stresses $< 0{\cdot}8\ \tau_m$, based on available experimental evidence. On the assumption of isotropy, these models can be combined for any stress and strain conditions. The predicted behaviour for one-dimensional compression, in which a laterally confined cylindrical sample is subjected to a uniform axial stress, is in reasonable, but not exact, agreement with the observed data. The generally used analysis of one-dimensional compression data is based on the assumption that the structure of the clay particle behaves as an isotropic elastic material for any given increment of load. The inclusion of anisotropic considerations is of excessive mathematical complexity.

The study of the rheology of clay soils is still at a preliminary stage, and much detailed experimental work remains to be done before further progress can be made. The use of apparatus enabling precise measurement of the imposed conditions is essential.

The next meeting of the Club will be held at the Technological Research Station, Spillers, Ltd., Station Road, Cambridge, on May 7, when Mr. R. G. King (Farol Research Engineers) will speak on "Viscoelasticity and the Weissenberg Rheogoniometer". The instrument will be available for the two days following the meeting for practical demonstrations on materials which members of the Club or visitors are invited to submit. Notice of this should be given in advance to the Secretary of the Club at the above address. H. G. MULLER

PHENOLIC ALKALOIDS

A SYMPOSIUM organized by the Plant Phenolics Group was held at the School of Pharmacy, University of London, on January 9, and was concerned with the alkaloids of the opium poppy and of ipecacuanha.

Under the chairmanship of Prof. W. O. James a paper on the distribution and significance of alkaloids in *Papaver somniferum* was presented by Prof. J. W. Fairbairn (School of Pharmacy, University of London). The work in his laboratory was chiefly a study of the occurrence of alkaloids in relation to the origin and distribution of laticiferous vessels and an analysis of the latex composition using samples drawn at short intervals from unripe capsules. It was confirmed that alkaloids were restricted to laticiferous vessels and also shown that this anastomizing system always occurred in the phloem, but was absent from stamens, ovules, seeds and seedlings up to the cotyledon stage. Latex from capsules had been assayed for morphine, caoutchouc and total solids, and it was shown that rapid changes in the composition of the latex took place in short periods of time such as 2 hr. Similar rapid changes had also been shown to take place in the fruit of *Conium maculatum* (Fairbairn and Suwal). From anatomical and qualitative chemical results it had been suggested that the alkaloids might be products of photosynthesis, secreted into the laticifers and so removed from metabolic circulation. This 'drain-pipe' theory now appeared unlikely owing to the rapid alkaloidal variation, and further work might raise the status of the latex from that of a slowly growing heap of 'metabolic sewage' to that of a living entity, actively participating in the metabolism of the plant.

Biosynthesis of Opium Alkaloids. An account of the studies which have been carried out in several laboratories was given by Dr. A. R. Battersby (University of Bristol), who was responsible for recent work at Bristol involving the feeding of growing plants with tyrosine, labelled specifically with carbon-14. Unambiguous degradation of carefully purified alkaloids, isolated from the plant, had shown that the molecule of papaverine was specifically labelled at positions 1 and 3 and morphine at the corresponding positions 9 and 16. These results were interpreted as showing that two aromatic units with a two-carbon side-chain (*Ar*–C–C) constitute building blocks in the carbon(16) skeleton of the alkaloids studied. Supporting evidence was available by synthesis of norlaudanosoline specifically labelled with carbon-14, which was incorporated into papaverine and morphine by feeding experiments. Furthermore, results of controlled degradation of the latter radioactive alkaloids showed little doubt that the rings *A* and *C* of morphine are joined by a phenolic coupling reaction between two aromatic rings. Rate studies on the incorporation of activity into the two alkaloids from carbon-14 carbon dioxide (Rapoport *et al.*) and from specifically labelled tyrosine (Bristol workers), together with other evidence, had shown that the alkaloids are formed in the order thebaine–codeine–morphine. Concluding his account of recent work, Dr. Battersby was able to show that the present evidence was in keeping with the view that the opium alkaloids are products of the shikimic–prephenic acid pathway, the two *Ar*–C–C units produced by this route being used to provide the sixteen carbon atoms required for skeletons of the bases. It was probable that the units were different, yet derivable from tyrosine in the living plant.

Chemical Structure and Pharmacological Activity. In the afternoon session Prof. W. B. Whalley (School of Pharmacy, University of London) introduced Dr. N. J. Harper (Chelsea College of Science and Technology), who discussed the relationships between structure and pharmacological activity of morphine and related substances. He stated that morphine had been modified chemically in many ways in attempts to reduce undesirable side effects, namely, liability to produce addiction and depressant effect on the respiratory centre, but such modifications had not yet resulted in a compound which had significantly replaced morphine as a clinical agent. The alternative approach of synthesizing fragments of the morphine molecule had resulted in the production of the morphinans and benzomorphans which represented the greatest achievements in this direction. These studies clearly emphasized the importance of the phenolic, alcoholic and basic groupings. Stereochemical factors played an important part in analgesic activity since, with enantiomorphs, one isomer was always more active than the other and in some synthetic analgesics the most active enantiomorphs were related to D-(–)-alanine. Various studies had led to the hypothesis that in the mediation of analgesic activity a three-dimensional fit at a 'receptor site' was involved and stereochemical implications could be important in the separation of desirable and undesirable pharmacological effects. It was probable that the chief factor limiting the intensity of response and duration of effect of morphine and the synthetic analgesics was biotransformation, and in these transformations the phenolic grouping played an important part. *N*-dealkylation also had important pharmacological implications following from two provocative hypotheses; one relating it to analgesic action, and the other to the development of tolerance.

Chemistry and Biosynthesis of Ipecacuanha Alkaloids. Dr. H. T. Openshaw (Wellcome Research Laboratories, Beckenham, Kent) dealt chiefly with the chemistry of the alkaloids and said that they formed a group of inter-related isoquinoline alkaloids of unique structure, the biogenetic relationship of which to the benzylisoquinoline group was of particular interest. The structure of emetine was established by classical methods of degradation, but in its final stages this investigation received powerful support from the developments in biogenetic theory then current; in turn, the biogenetic theory was strongly upheld by the discovery in ipecacuanha of a postulated intermediate in the biosynthesis. Considerable significance was also attached to the stereochemistry of the alkaloids and their relationship to that of the cinchona and indole series. The absolute configuration of each of the four asymmetric centres in emetine had been established, and attention had been paid to the problem of stereospecific synthesis of the alkaloid. A feature of special interest in the chemistry of emetine was its conversion by mild oxidation into a series of dehydrogenation products, the structure of which had been elucidated.

Pharmacologically, emetine was of considerable importance for its amœbicidal activity, and of special interest in that all the stereoisomers and closely related compounds arising from the synthetic work, only one other substance, 2-dehydroemetine, showed comparable activity.

The symposium therefore proved to be well balanced and showed the value of studies on the location and variation in alkaloids of opium, as a background to results obtained using tracer techniques. Classical chemical investigations, in particular with stereochemical considerations, were of benefit to pharmacology and the work on the ipecacuanha alkaloids formed an interesting comparison with studies on morphine and its related compounds.

THE NATIONAL PARKS COMMISSION

THE twelfth annual report of the National Parks Commission, for the year ended September 30, 1961, besides providing the customary concise and very readable illustrated account of the activities of the Commission during the year, progress in the national parks and with the long-distance routes, is marked by two notes of anxiety*. First, the Commission is anxious that amending legislation to the National Parks Act of 1949 should not be long delayed. Apart from the practical benefit expected to follow the adoption of the recommendations submitted to the Minister, the Commission believes that reappraisal in Parliament of the working of the Act would give welcome encouragement to those whose duty it is to administer the Parks and would help to produce in the public mind a clearer conception of the whole idea of national parks. The second note of anxiety relates to the continuing proliferation of aerial masts throughout the countryside, usually on remote and unobstructed high ground. These increasing coverage demands appear as yet to be entirely unco-ordinated, and while the Commission recognizes the need, it is far from satisfied that the problem of mast-sharing receives adequate consideration.

The magnitude of the development issue is shown by the fact that during the year nearly 450 proposals for development affecting landscape beauty in national parks, in areas of outstanding natural beauty, or elsewhere were referred to the Commission by Government departments, park or other local planning authorities, or by amenity organizations. One notable success during the year recorded in the report is the decision of the North-Western Electricity Board to place the entire Upper Borrowdale scheme underground at its own expense, notwithstanding the offer of contributions from the Friends of the Lake District and the official consent to the placing of certain sections of the line overhead. Regarding areas of outstanding natural beauty, the report comments that review of the work done by the local planning authorities indicated that while the preservation of these areas from unsightly development was receiving full attention, insufficient use was made of the opportunities for positive action for the enhancement of natural beauty which would earn payment of the special 75 per cent rate of Exchequer grant. Some progress is reported with the long-distance routes, notably with the Dorset Coast Path, on the South Downs route, and field work on a North York Moors and a Yorkshire Court Path. One of the two remaining major problems of the Pennine Way has been solved, completing the Path within the Peak District National Park.

IMMUNOLOGICAL FUNCTION OF THYMUS AND BURSA OF FABRICIUS

Thymus Lesions in an Auto-immune Disease of Mice

A STRAIN of mice, *NZB/BL*, has been shown by Bielschowsky *et al.*[1] to develop a hæmolytic anæmia of auto-immune type, usually around 6–7 months of age. Through their co-operation we have had this strain of mice available for investigation during the past two years and have fully confirmed their findings. As judged by the occurrence of a positive direct Coombs test on the red cells, the condition can be transferred to young isologous mice by transfer of splenic cells from an older animal showing the typical signs but not from similar numbers of cells from mice in the pre-symptomatic stage[2].

It is well known that in about 70 per cent of human cases of myasthenia gravis the thymus contains numerous lymph follicles with typical germinal centres[3] and that in a significant proportion of early cases thymectomy cures or greatly alleviates the disease. Simpson[4] and Strauss *et al.*[5] have considered the condition a manifestation of auto-immune disease. We have, therefore, recently examined thymus sections from most of the mice of the *NZB/BL* strain being killed for transfer experiments or for other reasons. More than half have shown appearances which we interpret as lymph follicles with germinal centres and which have a close resemblance to the histological findings in typical human cases of myasthenia gravis (Fig. 1).

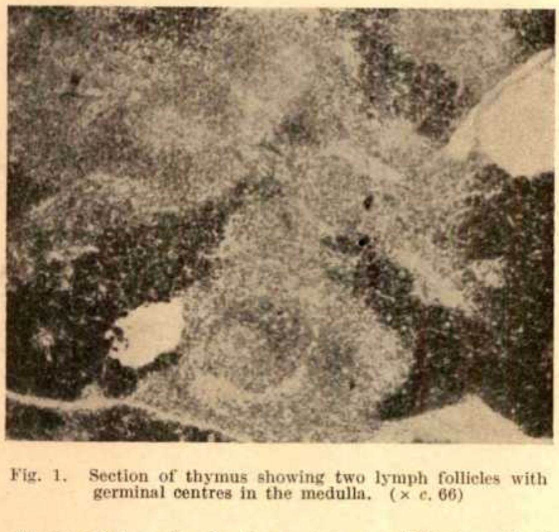

Fig. 1. Section of thymus showing two lymph follicles with germinal centres in the medulla. (× c. 66)

Many of the mice in the series were killed routinely when moribund, and in these there was severe involution of the thymus from age and stress, usually with complete atrophy of the cortex. Some of these showed an excess of lymphoid cells in the medulla; but the most striking feature was that in all mice more than 9 months of age in which the thymus cortex was still clearly shown, lymph follicles in the medulla were present. The usual appearance was of a complex area showing two or more germinal centres with incomplete surrounding crescents of mature small lymphocytes. It was characteristic to see small areas or cords of close-packed small lymphocytes, presumably representing over-filled intrathymic lymphatic channels.

These findings will be more fully described and their significance discussed in another publication. Here we wish merely to consider them briefly in relation to recent work[6] which suggests that the thymus is an essential primary source of stem cells for the development of immunologically competent cells in spleen and lymph nodes. It has been claimed[7] that auto-immune disease is a manifestation of the activity of 'forbidden clones' of cells unresponsive to the normal homeostatic controls which prevent the development of cells reactive against body constituents. If the site of origin of such forbidden clones is the thymus, they might well be expected to show their forbidden quality by proliferation as a germinal centre in a region where such activity never normally takes place.

We are also interested in the possible analogy between the condition manifested in our strain *NZB/BL* as auto-immune disease and the emergence of lymphoid leukæmia in mice of the high-leukæmia strain *AKR*. In the latter the first appearance of the forbidden (malignant) clone is almost regularly in the thymus and the incidence of leukæmia is greatly reduced by thymectomy at an early age.

Active experimental work based on these ideas and analogies is in progress.

Dissociation of Immunological Responsiveness in Fowls with a Hormonally Arrested Development of Lymphoid Tissues

IN recent months there has been evidence of an increasing interest among immunologists in the role of the thymus in the development of immunological functions. Several workers[1-3] have independently expressed the view that precursors of immunologically competent cells arise wholly or mainly in the thymus, moving out during the first weeks of life to colonize other lymphoid organs such as spleen and lymph nodes, where they become available for the various types of immunological function.

Experimental evidence supporting this view has been presented by Miller[2], in showing that thymectomy of one-day mice allowed them to accept homografts for up to 60 days. Archer and Pierce[4] have also shown that thymectomy of rabbits at 5 days removed the ability to produce antibody in response to a standard antigenic challenge later in life.

In chickens, removal of the bursa of Fabricius in the first week of life similarly prevents any antibody response to appropriate challenge.

The work to be reported in this communication is concerned with studies on 'hormonally bursectomized' chickens. Prevention of the development of the bursa was achieved by the administration of 2·5 mgm. of testosterone propionate (B.D.H.) to the allantoic cavity of the 12-day chick embryo, the bursal changes resulting from this having been previously described[5]. Chickens treated in this manner are termed bursaless in this communication.

The resulting changes in other lymphoid tissues are more varied. The thymus appears histologically normal in about 60 per cent of bursaless chickens. The remainder show a variety of changes, ranging from a moderate atrophy of the cortex (30 per cent) to a group with complete cortical atrophy and severe degenerative changes in the medulla (10 per cent). In most bursaless chickens, the weight of the spleen is about half the normal value, and histological examination shows a relative absence of lymphoid tissue and plasma cells, although active lymphoid follicles are visible. It is only in bursaless chickens with a complete atrophy of the thymic cortex that these follicles are greatly reduced in number. Small lymphocytes in blood were present in normal amounts in most bursaless chickens, and again it was only in those with severe thymic atrophy that the number was reduced to about one-third.

Our initial experiments involved a repetition of the work of Mueller *et al.*[6], in challenging hormonally bursectomized chicks with several standard antigens, and the results obtained were in complete agreement, no antibody at all being produced. As many of these chicks had a morphologically normal thymus, it was decided to determine if other types of immunological reactivity persisted in these birds. Studies were made on: (1) the ability of the blood to produce lesions on the chorioallantoic membrane[7]; (2) the rejection of skin homografts; (3) the tuberculin reaction as an example of delayed hypersensitivity. These tests, together with the response to bovine serum albumin, were carried out on normal, bursaless, and bursaless chickens with atrophic thymuses. Birds in this last group are relatively rare as most die early in life, and only a few figures are at present available. The results are presented in Table 1.

Table 1. IMMUNOLOGICAL RESPONSES OF NORMAL AND BURSALESS CHICKENS

Type of reaction	Normal chickens	Chickens treated with testosterone *in ovo*	
		Bursaless	Bursaless with atrophic thymus
CAM lesions:	*2,000 ± 800*	*1,900 ± 800*	*2,600 ± 100*
Large lymphocytes per focus	(35)	(10)	(2)
Homograft rejection:	*7 ± 1 day*	*7 ± 1 day*	Grafts intact at time of death* (2)
Average time of rejection	(12)	(12)	
Delayed hypersensitivity:	*positive*	*negative*	N.T.
Tuberculin reaction	(3/3)	(3/3)	
Antibody production:			
Incidence of positive titres	*100 per cent*	0 per cent	0 per cent
Mean reciprocal titres	320 (50)	<10 (40)	<10 (10)

N.T., not tested. Figures in brackets show the number of birds tested. Results in italics indicate positive (normal) reactivity.

* 20 and 24 days after grafting.

It can be seen from the results that the types of immunological response of which the bird is capable depend on the extent to which the primary lymphoid organs, thymus and bursa, have developed in the treated chickens during the first weeks of life.

The influence of the hormone is not a simple quantitative reduction of all immunological responses, but rather a selective eradication of some, leaving others intact, which in turn may be absent in more severely affected animals.

The dissociation between the different types of immunological reactivity achieved in this system indicates at least two basic levels of immune response, related functionally in the fowl to different primary lymphoid organs. In the order of disappearance of these functions under the influence of the hormone, the first level is associated with the production of circulating antibody and delayed hypersensitivity. The common denominator between these responses is that they are both concerned with extrinsic microorganismal and similar antigens. The bursa of Fabricius appears to be primarily responsible for these functions. The second level of immune response is concerned with the recognition of histocompatibility antigens. The ability to produce lesions on the chorioallantoic membrane probably represents the basic form of graft versus host reactivity, and the presence of the thymic cortex is essential if this is to be developed into the full complex of the mechanism of homograft rejection, and perhaps of graft versus host reactions as induced by one of the standard methods.

It seems to be more than coincidence that the order of maturation of the different immunological functions in the fowl follows the same order as the resistance to elimination by hormonal treatment. This order, according to reports in the literature and some of our own results, is as follows: Simonsen phenomenon, homograft rejection[8], and circulating antibody production. It seems possible that this order of maturation reflects the evolutionary development of immunological reactions[9].

The presence of both bursa and thymus makes the fowl a very convenient model for examining this concept of different levels of immunological activity. It would be more difficult to undertake this in mammals, if, as we suspect, the mammalian thymus has combined the functions of the avian bursa and thymus.

Further results and a more complete discussion will shortly be published elsewhere.

This work was supported by research grants from the National Health and Medical Research Council, Canberra, and we are grateful to Sir Macfarlane Burnet for helpful discussions during the course of the investigations.

GENETIC NATURE OF TOLERANCE OF *HYPOMYCES SOLANI* F. *CUCURBITAE* TO PENTA- AND TETRA-CHLORONITROBENZENE

By S. G. GEORGOPOULOS

Department of Plant Pathology, University of California, Berkeley

IT is well known that a number of different fungi, when grown in the presence of chlorinated nitrobenzenes, give rise to sectors the growth of which is less inhibited by the fungistat than that of the original isolates[1-4]. Such relatively insensitive strains have been considered to arise by saltation[5] or mutation[2], but the nature of these changes has not so far been examined by means of genetic analysis. This might have been because of the absence of suitable sexual cycles in the particular organisms used. In many other cases of appearance of resistance to fungicides the mechanism of such an adaptation has been left a matter for speculation by the lack of data on genetic behaviour. Most investigators seem to believe that resistance which is not lost after serial transfers on a medium lacking the fungicide is mutational, while others[6] have presented some evidence that persistent adaptation does not always involve a change of a nuclear gene. In the work presented here the mutational origin of tolerance of *Hypomyces solani* f. *cucurbitae* Snyd. and Hans. to pentachloronitrobenzene (PCNB) and one of the isomers of tetrachloronitrobenzene (TCNB) has been established by crossing tolerant and sensitive strains and demonstrating a Mendelian segregation in the progeny.

The fungus is a well-known plant pathogen, causing root-, stem- and fruit-rot of cucurbits; it is heterothallic and occurs in four sex forms: hermaphrodites, females, males and neuters[7,8]. Different strains of race 1 of this organism[9], which had been maintained by single conidial transfers, were used in this work. The first PCNB-tolerant strains were obtained from fast-growing sectors which appeared in colonies on agar plates containing 0·3 per cent PCNB, a few days after mass transferring. All these tolerant strains grow almost twice as fast as their parent isolates in the presence of PCNB. Furthermore, they are all tolerant to 1,2,4,5-tetrachloro-3-nitrobenzene, a sample of which was given to me by Dr. W. A. Kreutzer of the Shell Development Co. In the presence of this latter material the difference between tolerant and sensitive strains is more clear-cut since tolerant strains grow at least ten times as fast as their parents. Tolerant strains have also been produced in the presence of TCNB. In one case an ascospore isolate of the sensitive type produced a tolerant sector 10 days after the germinated ascospore was transferred to a medium containing 0·2 per cent 1,2,4,5-TCNB. All these strains are also tolerant to PCNB.

A number of different tolerant strains was crossed with sensitive ones of the opposite mating type, some of the resultant perithecia were chosen at random and ascospores were germinated on water agar plates. Germinated random single ascospores were then plated on a medium containing 1,2,4,5-TCNB. The results of these experiments are summarized in Table 1. In crosses 1–3, protoperithecia of sensitive strains were fertilized with conidia of tolerant ones. In crosses 4 and 5 the protoperithecia of tolerant were fertilized with conidia of sensitive strains. In both cases tolerant strains reappeared in about 50 per cent of the progeny (Fig. 1). This demonstrates that, at least for the strains used, tolerance is controlled by a single gene. Small differences in the degree of tolerance of different segregants suggest the possible presence of modifying genes. The results presented in Table 2 show that ascospores from every one of the nine perithecia from cross No. 4 of Table 1, which were studied, segregated to tolerant and sensitive. This was also the case with all the other crosses. Therefore, the tolerant strains used apparently contain the gene for tolerance in all their nuclei. Evidence has also been obtained that tolerance segregates independently of sex. When protoperithecia of the sensitive strain 12 were fertilized with conidia of the sensitive strain 4, no tolerant ascospore isolates were obtained though 104 asco-

Bottom rows, some of the colonies which resulted from single ascospores from cross 12*a* × 4. Ascospores placed on different plates were taken from different perithecia

Table 1. SEGREGATION OF PROGENY FROM CROSSES BETWEEN STRAINS OF *H. solani* f. *cucurbitae* TOLERANT AND SENSITIVE TO PCNB AND 1,2,4,5-TCNB

Cross No.	Parents	Ascospores tested	Tolerant (T)	Sensitive (S)	Ratios T : S
1	14* × 10*a*†	225	115	110	1 : 0·957
2	9 × 30*a*	162	81	81	1 : 1
3	12 × 4*c*	178	92	86	1 : 0·935
4	12*a* × 4	194	100	94	1 : 0·940
5	12*c* × 4	272	130	142	1 : 1·092
		1,031	518	513	

* Strains represented by a number only are sensitive.
† Strains represented by a number and a letter are tolerant and have been derived from sensitives labelled with the same number.

Table 2. SEGREGATION FOR TOLERANCE TO PCNB AND 1,2,4,5-TCNB IN PROGENY FROM A CROSS BETWEEN STRAINS 12*a* AND 4 OF *H. solani* f. *cucurbitae*

Perithecium No.	Ascospores tested	Tolerant	Sensitive
1	18	8	10
2	16	8	8
3	34	14	20
4	18	10	8
5	36	24	12
6	18	4	14
7	18	13	5
8	18	9	9
9	18	10	8
	194	100	94

spores from different perithecia were tested. On the other hand, all 120 ascospores from a cross between two tolerant strains, 12*c* and 4*c*, that were studied, produced tolerant colonies. This indicates that the two strains crossed apparently contain the same gene for tolerance. The possibility that different tolerant strains might contain genes for tolerance at different loci is now being investigated.

This is believed to be the first instance in which tolerance of a plant pathogenic fungus to a commercially used fungicide has been shown to be transmitted through the sexual cycle and its genetic nature established by means of genetic analysis.

By inoculation tests strains 14 and 10*a*, and also 20 of the ascospore isolates which were obtained from the cross 14 × 10*a* and of which 10 were tolerant and 10 sensitive, were all found to be pathogenic to ripe banana squash fruits. Passage through such a host was not found to alter the tolerance or sensitiveness of the strains.

I thank W. C. Snyder, R. E. Reichle and James V. Alexander for helpful suggestions.

ELECTROPHORESIS OF SERUM AND SOLUBLE LIVER PROTEINS ON CELLULOSE ACETATE

By F. A. MULLAN, D. M. HANCOCK and D. W. NEILL
Department of Surgery, The Queen's University, Belfast

WE have been working on the electrophoresis of soluble liver proteins in order to find a satisfactory method for the study of biopsies from patients with liver disease. We began by using rat liver and have varied the duration of the electrophoresis, the site of application of the sample, and the buffer systems during the course of this work. When veronal buffer (pH 8·6) was used with an overnight run (16 hr.), a better separation of the protein bands was obtained when the sample was applied 2·5 cm. from the anode end of the strip ('anode application') than when it was applied the same distance from the cathode end ('cathode application'). We shall describe the work we have done on 'anode application' of serum and soluble liver proteins to elucidate the patterns obtained with this unorthodox procedure.

Liver. There are several different methods for the production of clear, concentrated and undenatured solutions of soluble cell proteins from solid organs[1-7]. We have used the following method for rat liver. It was perfused with 0·15 N saline at 37° C. with the rat still living under ether anæsthesia[8]. The organ was then removed, cut up into small slices and homogenized in a Tower's hand homogenizer, in the cold, with a volume of saline equal to the weight of the liver. The homogenate was then centrifuged at 60,000g for 1½ hr. in a refrigerated centrifuge. The clear supernatant was brought to a pH of 5·1–5·2. At this pH precipitation of the major enzymatic fractions occurs[9], the removal of which prevents denaturation of the remaining soluble proteins in the clear supernatant obtained by a final centrifugation at 3,000g. We have routinely applied the sample 2·5 cm. from the anode and 2·5 cm. from the cathode ends of alternate cellulose acetate strips in a horizontal Shandon tank in more than 100 electrophoretic runs. Fig. 1 is an example of the pattern obtained with an overnight run using veronal buffer. There are four main bands with 'cathode' and five with the unorthodox 'anode application'. 'Anode application' results in migration of the sample away from the application site towards the cathode and improved separation of each fraction. The use of a water seal to cut down evaporation makes little difference to the result.

Serum. In contrast to the results obtained with liver, 'anode application' of human serum using the

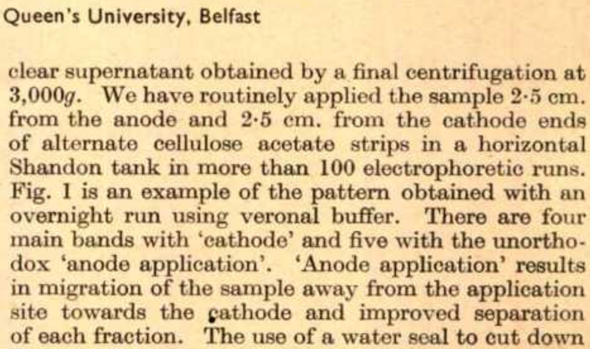

Fig. 1. Electrophoretic separation of the soluble liver cytoplasmic proteins of the rat. The 'cathode end' is on the left. Veronal buffer, pH 8·6, μ = 0·1, 90 V., 0·4 m.amp./cm., 16 hr. Upper strip = 'anode application'

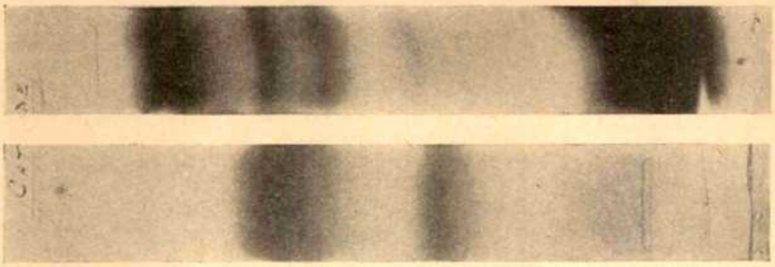

Fig. 2. Electrophoretic separation of human serum using the same conditions as in Fig. 1. The 'cathode end' is on the left. Lower strip = 'anode application'

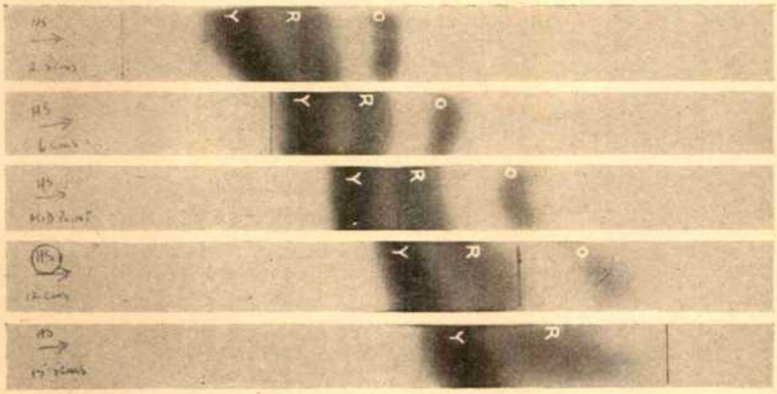

Fig. 3. Electrophoretic separation of fluorescein conjugated crude globulin fraction of immune rabbit serum with variation of application points. The 'cathode end' is on the left. Veronal buffer, *p*H 8·6, $\mu = 0{\cdot}1$, 150 V., 2 hr. The sites of the coloured bands (R = red, Y = yellow, and O = orange) have been marked and the strip then stained with lissamine green. Protein staining bands correspond with the coloured bands

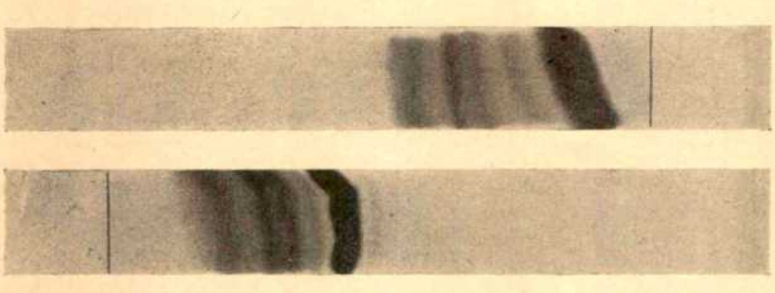

Fig. 4. Electrophoretic separation of human serum using *tris*–veronal buffer, 180 V., 0·4 m.amp./cm., 3 hr. The 'cathode end' is on the left. Upper strip = 'anode application'

same conditions (16 hr.; veronal buffer) produces only two bands instead of the usual pattern (Fig. 2).

We used a fluorescein conjugated crude globulin fraction of immune rabbit serum (Wellcome rabbit precipitating anti-guinea pig serum) to observe the migration of protein bands during electrophoresis. This fraction was obtained by the mixing of equal volumes of serum and saturated ammonium sulphate at 4° C. followed by centrifugation and solution of the precipitate in a little distilled water. The globulin fraction was dialysed at 4° C. against 0·15 N saline overnight and then conjugated with fluorescein isothiocyanate using the method of Marshall, Eveland and Smith[10]. On electrophoresis the conjugate split into three coloured bands: red, yellow and orange. These coloured bands correspond exactly with the protein fractions stained in the usual way. The effects of application of this conjugate at different sites along the strip are shown in Fig. 3. When the sample is applied 2·5 cm. from the anode end, the orange band, after an initial short movement towards the cathode, moves away towards the anode end of the strip, while the yellow and red bands move towards the cathode. Fig. 3 shows that the three protein fractions bear a consistent relation to each other wherever the sample is applied, but when the sample is applied nearer to the anode end the yellow and red bands start to separate 'backwards' towards the cathode. When the top and bottom strips in this figure are compared it is seen that the bands which show least movement forwards on 'cathode application' show the greatest movement 'backwards' on 'anode application'.

The study of fluorescinated globulins helped us to evaluate the pattern obtained with liver and serum (Figs. 1 and 2). The slowly moving globulin fractions in each case are those which migrate towards the cathode on anode application. All fractions in our preparation of rat liver behave in this way; but in the case of serum only two bands are obtained, as the faster moving fractions have moved off the strip towards the anode. The pattern obtained with the 'anode application' may be due to the fact that endosmosis and evaporation have a greater effect on the migration of some globulin fractions under these conditions than does the current.

The pattern with 'anode application' of serum can be changed by altering the electrophoretic conditions. Using *tris*–veronal buffer and a short 3½-hr. run we found that all fractions, including albumin, migrate towards the cathode (Fig. 4). Liver behaves similarly with the veronal and *tris*–veronal systems, but orthodox application with *tris*–veronal gives the better results.

Application of the sample near the anode end of a cellulose acetate strip may be of value in studying electrophoretic separation of protein fractions from other tissues provided that satisfactory buffer systems and timing of the run can be arranged to suit this unorthodox method.

NERVE SUPPLY OF THE PULMONARY BIFURCATION BARORECEPTOR AREA AND ITS SIGNIFICANCE

By Prof. JOHN A. BEVAN and M. ANTHONY VERITY

Departments of Pharmacology and Pathology, University of California Medical Center, Los Angeles 24

KOCH[1] was the first to interpret the significance of the anatomical location of the mammalian baroreceptor areas. He pointed out that the carotid and aortic baroreceptors are found in surviving areas in the mature animal of the visceral arch vessels of the embryo and each of these areas was innervated by the corresponding visceral arch nerve. The carotid sinus formed from visceral arch III is supplied by the glossopharyngeal nerve. The aortic arch pressoreceptor area derived from visceral arch IV is innervated by a branch of the superior laryngeal nerve, the nerve of visceral arch IV.

Recent investigations have revealed an aggregation of sensory endings, probably pressoreceptors at the bifurcation of the main pulmonary artery of the cat, which on stimulation cause reflex changes in heart-rate, vascular resistance and respiration[2-4]. As the anatomical nerve supply to this sensory area located on a vessel derived from visceral arch VI has not been described, dissections were carried out in ten cats to determine this. The nomenclature of Mizeres[5] will be adopted in this description. It was found that the recurrent cardiac nerve and sometimes the cranio-vagal cardiac nerves carry the main innervation of the pulmonary bifurcation and the adjacent parts of the main pulmonary artery and its right and left branches.

The recurrent cardiac nerve (*r.c.*) is a moderately large nerve arising from the right recurrent laryngeal nerve (*r.l.*) as it loops around the right subclavian artery. It usually receives a contribution of varying size from the vagal trunk (*v.*) and another from the stellate ganglion. The nerve passes dorsally to the anterior vena cava, laterally to the brachiocephalic artery and arch of the aorta, to the pulmonary bifurcation where it divides into anterolateral and posterolateral branches. The anterolateral branch is the smallest. These branches fan out over the anterior and posterior aspects of the main pulmonary artery (*p.a.*) and communicate with plexi around the right and left pulmonary arteries and the pretracheal plexus. Some fibres continue to the heart and the coronary plexi. During its course it communicates freely with the cranio-vagal cardiac nerves (*c.v.c.*). The right vagal cardiac nerves arise from the right vagus trunk caudal to the origin of the right recurrent laryngeal nerve. They fall into two groups—the cranial and caudal vagal cardiac nerves. These vary in size, number and course. Some of the smaller divisions may be seen only with the aid of a dissecting microscope. They supply twigs to the right pulmonary artery plexus, the antero- and postero-lateral branches of the right recurrent cardiac nerve at the pulmonary bifurcation and to the plexus formed by the ventral branch of the vagus, anterior to the pulmonary root, and then terminate in the atrial wall. Small twigs, variable in size and position and sometimes absent, are supplied to the pre-tracheal plexus and the plexus around the right and left pulmonary artery by the right stellate cardiac nerves, the ventromedial cervical cardiac nerve, the left recurrent laryngeal nerve and the ventral branch of of the left vagal trunk. Other twigs are supplied from a diffuse plexiform network of fibres from the ventrolateral cardiac nerve and the left stellate cardiac nerve.

Of all these nerves, the recurrent cardiac nerve is undoubtedly the most important and constant. Nonidez[6] states that in the dog the recurrent cardiac nerve contains pre-ganglionic, afferent and sympathetic post-ganglionic fibres. The recurrent cardiac nerve is a branch of the right recurrent laryngeal nerve, the nerve of visceral arch VI (ref. 7). It is therefore of considerable interest that the main nerve supply to the pulmonary bifurcation sensory area, part of visceral arch VI, is derived from the recurrent laryngeal nerve, the nerve of visceral arch VI. As the most cephalic part of the pulmonary

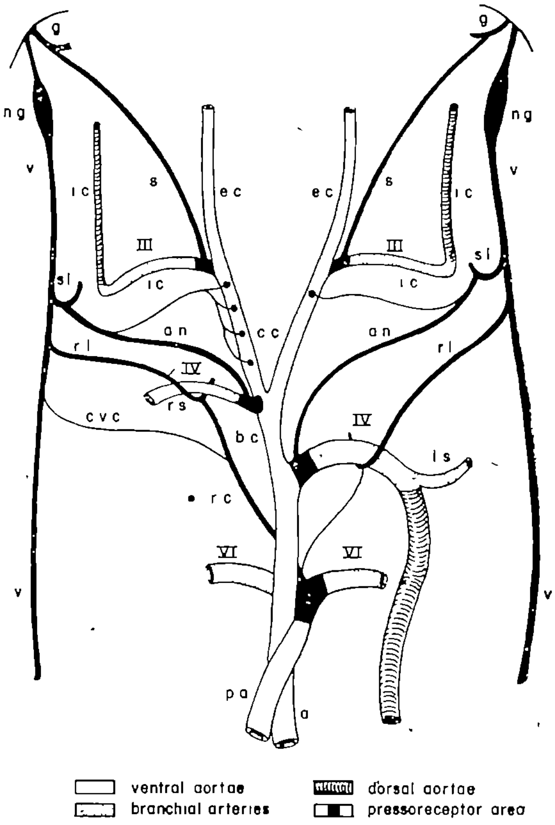

Fig. 1. Diagrammatic representation of the localization and innervation of the pressoreceptor areas of the cat in relation to the embryological derivation of the vessels

a, Aorta; *a.n.*, aortic nerve; *b.c.*, brachiocephalic artery; *c.c.*, common carotid artery; *c.v.c.*, cranio-vagal cardiac nerve; *e.c.*, external carotid artery; *g.*, glossopharyngeal nerve, *i.c.*, internal carotid artery, *l.s.*, left subclavian artery; *n.g.*, nodose ganglion; *p.a.*, pulmonary artery; *r.c.*, recurrent cardiac nerve; *r.l.*, recurrent laryngeal nerve; *r.s.*, right subclavian artery; *s*, sinus nerve; *s.l.*, superior laryngeal nerve; *v*, vagus

artery is formed from the posterior and right lateral parts of the bulbus cordis[8], it is reasonable that this vessel should be predominantly supplied from the right visceral nerve VI.

In addition to this pulmonary area, other pressoreceptor areas in the cat have been described since the publication of Koch's monograph. The bilateral common carotid areas at the level of the origin of the superior thyroid arteries[9], small discrete areas on the right common carotid[6] and others at the bifurcation and adjacent parts of the wall of the brachiocephalic trunk[10] have been found. All are supplied by branches that emerge from the superior laryngeal or aortic nerves.

In Fig. 1, the probable embryological origin of some of the larger arteries of the upper thorax and neck of the cat is represented. The ascending aorta, pulmonary artery, brachiocephalic trunk and the common and external carotid arteries are derived from the embryonic ventral aortæ. The vessels of visceral arch III are represented by the internal carotid arteries (not patent in this animal); those of visceral arch IV by the subclavian arteries and the arch of the aorta; those of visceral arch VI by the right and left pulmonary arteries[11].

It is of interest that in the mature animal a pressoreceptor area is found near the junction of each surviving visceral arch artery, with an artery derived from the ventral aortæ. The carotid sinus lies at the junction of the internal carotid and common carotid arteries, the brachiocephalic areas at the junction of the subclavian and brachiocephalic arteries, the aortic area at the junction of the aortic arch and ascending aorta and the pulmonary artery bifurcation area at the junction of the right and left pulmonary arteries with the main pulmonary artery. These areas include all the known pressoreceptors except those in the walls of the common carotid arteries and the main pulmonary artery, which are derived from the embryonic ventral aortæ. Nonidez[6] states that the afferent endings found in the ascending aorta are probably proprioceptor in type.

The presence of pressoreceptors in the ventral aortæ and at the junction of all visceral arch vessels and the ventral aortæ is most significant in relation to the comparative anatomy, embryology and physiology of this area[12]. It is in keeping with the hypothesis of Koch, which now deserves greater credence, as it may now be applied to all known pressoreceptor areas in the cat.

EXISTENCE OF AN ERYTHROPOIETIC LABILE IRON POOL IN ANIMALS

By Dr. MYRON POLLYCOVE and Dr. MOHAMMAD MAQSOOD*

Donner Laboratory, University of California, Berkeley

During recent years the use of radioiron (iron-59) as a tracer has elucidated some fundamental aspects of the physiology and biochemistry of iron kinetics. Pollycove and Mortimer[1] have proposed mathematical models to explain the major pathways of iron kinetics in man (Fig. 1). The intercompartmental rate constants from compartment i to compartment j, α_{ij} are calculated from the measured slopes (r_1, r_2, r_3), intercepts (A, B, C), and fraction of radioiron irreversibly fixed in maturing erythrons. The amounts of iron in the labile pools are calculated from these intercompartmental rate constants and direct measurement of total plasma iron. Iron for hæmoglobin synthesis is the product of the fraction of erythropoietic labile iron pool irreversibly fixed in maturing erythrons, α_{23}, and the amount of iron in the erythropoietic labile iron pool. The intercompartmental rate constant α_{23} determines the rate at which iron in the erythropoietic labile pool is converted into hæm iron.

The concept of a labile erythropoietic iron pool[1] is of chief importance to these models. So far, no physiological or biochemical entity corresponding to such a labile iron pool has been demonstrated. In the present series of experiments, an attempt was made to examine some components of iron kinetics in the dog and rabbit, with the view of demonstrating the existence of an erythropoietic labile iron pool.

Fig. 1. General iron kinetics model

---

* Visiting Research Scientist from Pakistan.

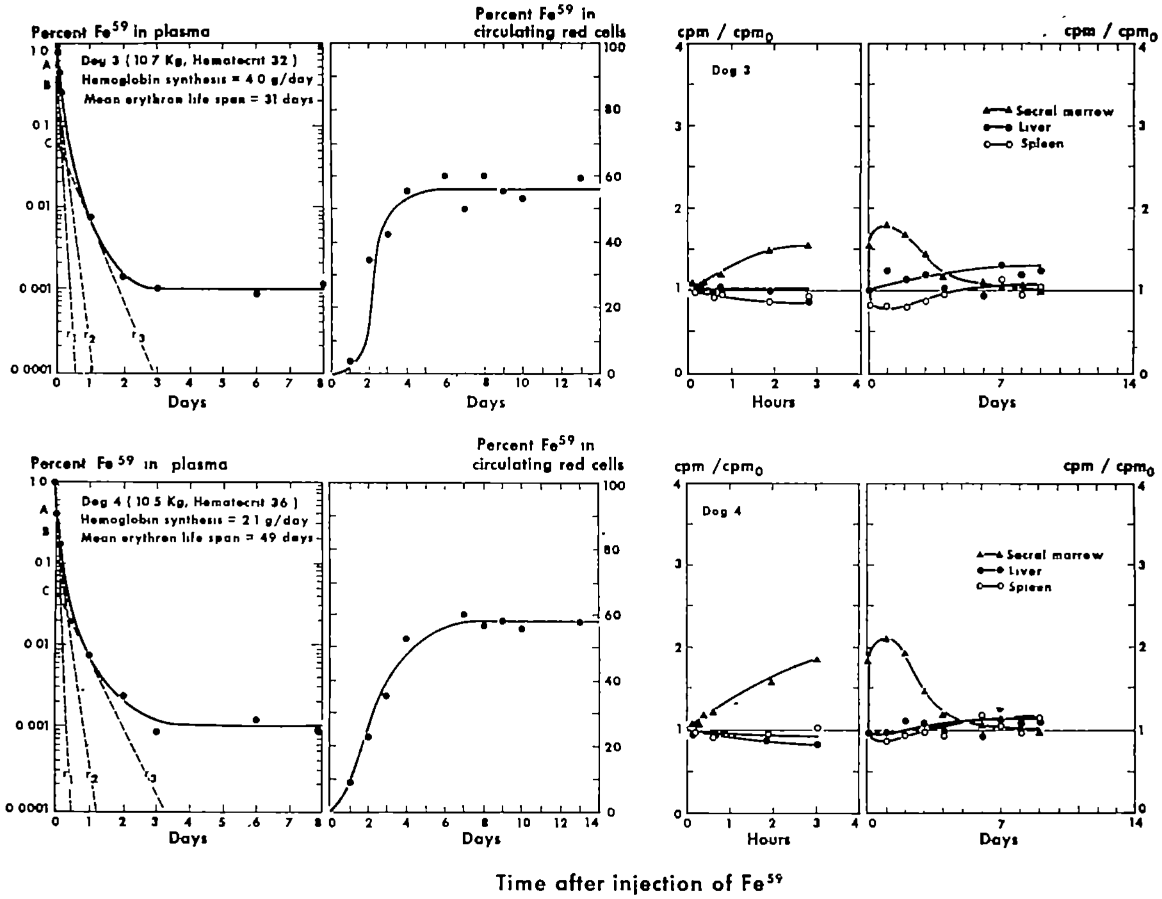

Fig 2. Iron kinetics data of dogs 3 and 4. Intercompartmental rate constant a_{32} is calculated from measurements of the slopes r_1, r_2, r_3, their intercepts A, B, C, and the fraction of radioiron fixed in maturing erythrons, f

Graded doses of 2·5 per cent aqueous solution of phenylhydrazine were injected subcutaneously in rabbits to produce reticulocytosis. For each experiment 30–100 μc. of radioiron (supplied by Abbot Laboratory, Oak Ridge), as ferrous citrate specific activity 3–12 μc./μgm., were incubated at 37° C. for ½ hr. with sufficient quantity of fresh plasma from dog/rabbit, to ensure binding of all iron to the β_1-globulin transferrin. After incubation, a measured amount of plasma labelled with iron-59 was injected intravenously in the dog/rabbit and blood samples were collected from the dog/rabbit at different time intervals depending on the nature of the experiments. The experimental animals were then killed and samples of blood, bone marrow, ribs, rib-marrow and pieces of liver and spleen collected for biochemical studies. Radioactivity in the different biological samples was measured by counting 1–2 ml. aliquots in a scintillation well counter.

Complete iron kinetics investigation were made in two dogs for a period of ten days as described by Pollycove[2] and Pollycove and Mortimer[1]. By applying the mathematical model to radioiron measurements of plasma, red cells, liver, spleen and sacral marrow, the intercompartmental rate constant was calculated for transfer of iron from the erythropoietic labile iron pool to erythron iron irreversibly fixed for hæm synthesis (Fig. 2).

The results from eight experimental dogs (dogs 1, 2, 5–10) showed that marrow radioiron was associated with cellular elements. Doubly crystallized hæm was prepared from marrow aspirations of femur, marrow scrapings from ribs and intact rib homogenates of dogs after hæm synthesis was arrested with 5 × 10^{-4} M lead acetate. Analysis of results showed that soon after injection of labelled plasma,

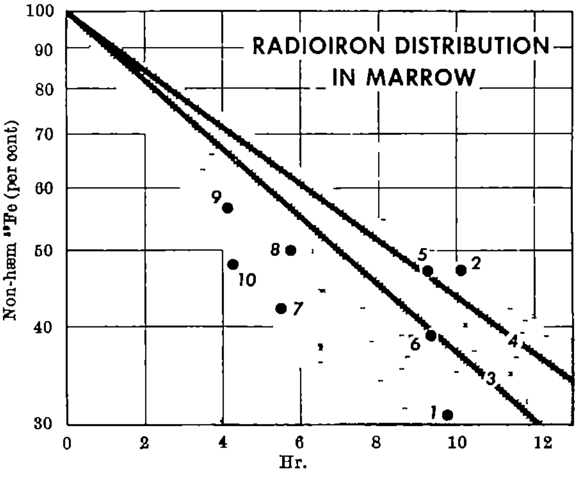

Fig. 3. Radioiron distribution in marrow. Points for dogs 1, 2, 5–10 were obtained from direct analysis of red marrow including measurement of iron-59 specific activity of double crystallized hæm. The slopes for dogs 3 and 4 are the calculated intercompartmental transfer-rates from the erythropoietic labile iron pool to irreversibly fixed erythron iron, a_{32}. These rate constants were calculated by analysis in accordance with the mathematical model (Fig. 1) of plasma radioiron data shown in Fig. 2

Post-venesection plasma	329	3·2
Normal plasma	186	2·6
Acid–citrate–dextrose solution	0	1·7

marrow radioiron occurs chiefly in non-hæm form, 8 hr. after injection (6 hr. after most of the radioiron initially in the plasma had accumulated in marrow) approximately half the marrow radioiron was present as erythron non-hæm radioiron (Fig. 3). Afterwards, increasing amounts of erythron radioiron occurred in hæm as non-hæm radioiron decreased. The calculated rates of transfer of radioiron from labile non-hæm iron to fixed hæm iron in dogs 3 and 4 (Fig. 2) are in good agreement with the direct marrow analyses in the other eight dogs (Fig. 3). The non-hæm radioiron was largely associated with red cell membrane, while hæm radioiron was present almost entirely in the interior of the red cell (Table 1). In the case of phenylhydrazine-treated rabbits with 90 per cent reticulocytes, reticulocytes labelled with iron-59 were obtained by venesection 30 min. after the intravenous injection of a tracer amount of transferrin-bound radioiron. Subsequent incubation of these washed (three times with unlabelled plasma) labelled reticulocytes with unlabelled rabbit plasma and acid citrate dextrose solution demonstrated considerable transfer of reticulocyte radioiron back to plasma and significantly less to the acid citrate dextrose solution (Table 2). The data on rabbit erythrocytes and canine marrow indicate that a labile erythropoietic iron pool exists on the membranes of immature erythrons, and that this iron is derived from plasma transferrin-bound iron and transfers back to plasma, as well as transferring irreversibly into erythrons for hæm synthesis. Further work on man is being continued.

VARIATION IN GONADOTROPHIC HORMONE-LEVEL DURING ŒSTROUS CYCLE

By F. A. SOLIMAN and H. NASR

Department of Animal Physiology, Faculty of Veterinary Medicine, University of Cairo

SEVERAL investigators have attempted to bring anœstrous animals into œstrus followed by successful fertilization. The administration of pregnant mare serum or pituitary follicle-stimulating hormone followed by human chorionic gonadotrophin was successful in bringing ewes into heat, but only few of these animals produced lambs[1]. The administration of pregnant mare serum to mature rats and subsequent injection of human chorionic gonadotrophin was not very successful in inducing full œstrus and subsequent pregnancy after mating[2]. These facts called for the study of gonadotrophic hormone status during naturally occurring œstrous cycles.

Forty-eight mature female rats of an average weight of 180 gm. were used in this experiment. Vaginal smears were procured from these animals every 12 hr. for 20 days. They were then divided into six groups representing: procœstrus, early œstrus, late œstrus, metœstrus, early and late diœstrus. The animals were killed by decapitation under light ether anæsthesia. The blood collected from each animal was allowed to clot and then centrifuged at 4,000 r.p.m. for 15 min The sera from rats of the same groups were pooled. Steroid hormones were removed from the sera by using the procedure of Szego and Roberts[3]. The remaining serum proteins were then redissolved in saline to bring it back to the original volume of serum. The pituitary glands of each group of rats were weighed with a torsion balance then dried with acetone. Saline suspensions of the pituitary glands were prepared to contain 0·5 mgm. of fresh weight in every 0·1 ml. saline.

The total gonadotrophic hormone content of the sera and pituitaries was determined by using the chick method of assay[4]. Two groups of 15 chicks each, corresponding to every rat group, were given daily doses of 0·3 ml. serum or 0·5 mgm. pituitary for 4 days. One group was kept as control injected with saline. The weights of testes of chicks were used as a criterion of the gonadotrophic hormone content of the test material. The results were then expressed in terms of I.U. pregnant mare serum from a standard curve established under the same experimental conditions.

The follicle-stimulating hormone content of 0·5 ml. serum and 0·5 mgm. pituitary were assayed by the use of the luteinizing hormone augmentation method[5]. Two groups of 5 immature mice were allotted to each group of rats, one receiving serum while the other received pituitary saline suspension.

The luteinizing hormone content of 0·5 ml. serum and 0·5 mgm. pituitary was determined by Soliman's method[6]. Two groups of 5 immature female mice were used for each of the experimental rat groups. The follicle-stimulating and luteinizing hormone levels were expressed in I.U. from standard curves established under the same conditions, using standard preparations of pregnant mare serum and human chorionic gonadotrophin. The data were analysed statistically using the t or F values.

The total gonadotrophic hormone contents of the pituitaries did not show any significant variation during the œstrous cycle as judged from the analysis of variance. The total gonadotrophins present in the blood reached their highest level during the phases of procœstrus and early œstrus, then its level dropped during the other phases of the cycle (Table 1).

Table 1. TOTAL GONADOTROPHIC HORMONE IN RAT PITUITARY GLANDS AND SERUM DURING THE ŒSTROUS CYCLE

Phase of the œstrous cycle	Pituitary: Testes wt of chicks (mgm./100 gm. body-wt.)	Pituitary: I.U. (per mgm.)	Serum: Testes wt. of chicks (mgm./100 gm. body-wt.)	Serum: I.U. (per ml.)

± Standard error.

* Significantly different from late œstrus group at 5 per cent level of probability.

The pituitaries of procœstrous and œstrous rats had the highest concentration of follicle-stimulating hormone, and minimal amounts were present in the pituitaries of rats during the other stages of the cycle. In the blood there were two peaks of follicle-stimulating hormone, one being attained during early œstrus and the other during early diœstrus (Table 2).

Table 2. FOLLICLE-STIMULATING HORMONE CONTENTS OF RAT PITUITARIES AND SERUM DURING THE ŒSTRUS CYCLE

Phase of the œstrous cycle	Pituitary: Ovary wt of mice (mgm./100 gm. body-wt.)	Pituitary: I.U. (per mgm.)	Serum: Ovary wt. of mice (mgm./100 gm. body-wt.)	Serum: I.U. (per ml.)
Procœstrus	33·17 ± 3·00	0·73	27·16 ± 2·28	0·47
Early œstrus	31·71 ± 2·59	0·65	34·21 ± 3·45	0·78

F value	5·21		3·78	
Degrees of freedom	5, 29		5, 29	

± *S.E.*

The highest level of luteinizing hormone was observed in the pituitary glands during late œstrus. In the blood the luteinizing hormone level had two peaks, the higher one during late œstrus and the second during procœstrus.

It is concluded that the level of gonadotrophic hormone in the pituitary does not essentially parallel its concentration in the blood[7]. The luteinizing hormone level in the blood is relatively high at procœstrus, probably to augment the action of follicle-stimulating hormone, thus stimulating the growth of the Graafian follicles and secretion of œstrogen[8]. During late œstrus there is an increased rate of synthesis and release of luteinizing hormone to induce ovulation.

Table 3. LUTEINIZING HORMONE CONTENTS OF RAT PITUITARIES AND SERUM DURING ŒSTROUS CYCLE

Phase of the œstrous cycle	Pituitary: Average No. of corpora hæmorrhagica per mouse	Pituitary: I.U. (per mgm.)	Serum: Average No. of corpora hæmorrhagica per mouse	Serum: I.U. (per ml.)
Procœstrus	0·60 ± 0·13	0·42	1·33 ± 0·20	0·94

LACK OF RELATIONSHIP BETWEEN MITOCHONDRIAL OXIDATIVE PHOSPHORYLATION AND THE DICOUMAROL-SENSITIVE FLAVOENZYME 'DT DIAPHORASE' OR 'VITAMIN K REDUCTASE'

By LENNART DANIELSON and LARS ERNSTER

Wenner-Gren Institute, University of Stockholm

IT has recently been reported by Martius[1] that mitochondria from pigeon liver, a tissue previously[2] found to be devoid of the dicoumarol-sensitive flavoenzyme 'vitamin K reductase', exhibit phosphate/oxygen ratios with pyridine nucleotide-linked substrates which are one unit below the generally accepted value for mitochondria from various other animal tissues. With succinate as substrate, the phosphate/oxygen ratio was normal. These findings were taken by Martius as further support for his concept[3] that vitamin K reductase constitutes an obligatory link in the aerobic oxidation of pyridine nucleotide-linked substrates in intact, phosphorylating mitochondria.

In 1958, the occurrence in rat-liver of a highly active flavoenzyme catalysing the oxidation of reduced di- and tri-phosphopyridine nucleotide by artificial electron acceptors was detected in our laboratory[4]. The enzyme, called 'DT diaphorase', was afterwards partially purified, and its properties, among them a high sensitivity to dicoumarol, were investigated in some detail[5]. Investigations were also carried out on the relation of DT diaphorase to the terminal respiratory chain, using both isolated mitochondria[6,7] and liver slices[8]. In this work, unequivocal evidence has been obtained that DT diaphorase does not take part in the main enzymatic pathway of the aerobic oxidation of reduced pyridine nucleotides in rat-liver.

Until recently, DT diaphorase was believed to differ from vitamin K reductase, in spite of some conspicuous features in common between the two enzymes. This belief was based primarily on the fact that DT diaphorase exhibits no significant activity with vitamin K_1 as electron acceptor[5], whereas this compound has repeatedly been reported to serve as a highly active electron acceptor for vitamin K reductase[3,9]. Recently, however, Märki and Martius[1] have revised this property of vitamin K reductase, after having found that authentic samples of vitamin K_1 react only very slowly with their enzyme. In view of this finding, and of some other newly reported properties of vitamin K reductase[1], we were then led to conclude[7] that vitamin K reductase very probably is identical with DT diaphorase, and consequently, that Martius's concept[3] regarding the role of vitamin K reductase in cellular respiration and phosphorylation also may require revision. Singer and associates[10] have recently extracted a flavoenzyme from beef-heart electron transport particles which they on good grounds could identify with the flavoenzyme component of the phosphorylating mitochondrial diphosphopyridine nucleotide oxidase system. This flavoenzyme is specific for diphosphopyridine nucleotide and insensitive to dicoumarol, and thus distinct from DT diaphorase or vitamin K reductase, which further makes the validity of Martius's concept[3] doubtful.

The present article reports further data relevant to these problems, obtained in experiments with isolated pigeon-liver mitochondria. It is shown that these mitochondria are devoid of DT diaphorase, in accordance with the findings of Märki and Martius[1] concerning vitamin K reductase. At variance with Martius's findings[1], on the other hand, the present data reveal that pigeon-liver mitochondria exhibit phosphate/oxygen ratios with pyridine nucleotide-linked substrates which clearly exceed the value of 2, and are thus quite comparable with those usually obtained with mitochondria from other sources. It is also shown that dicoumarol uncouples phosphorylation from respiration in pigeon-liver mitochondria in the same fashion as it does in mitochondria from other sources, suggesting that this effect of dicoumarol is unrelated to its inhibitory effect on DT diaphorase or vitamin K reductase.

Liver mitochondria from pigeon (*Columba domestica*) were prepared by using essentially the same procedure as is routinely used in this laboratory[11] for preparing mitochondria from rat-liver. The mitochondria were washed twice with 0·25 *M* sucrose, whereby special care was taken in removing a sticky, dark-brown sediment which usually appeared as a tightly packed sediment beneath the more fluffy mitochondrial pellet. The final mitochondrial pellet was suspended in 0·25 *M* sucrose to contain mitochondria from 1 gm. wet-weight liver (about 26 mgm. mitochondrial protein) per ml.

Table 1. COMPARISON BETWEEN RAT- AND PIGEON-LIVER MITOCHONDRIA WITH REGARD TO THE DT DIAPHORASE DEPENDENT BY-PASS OF THE AMYTAL-SENSITIVE SITE OF THE RESPIRATORY CHAIN

Additions	Respiration, µatoms oxygen Rat	Pigeon
None	5·49	4 98
Vitamin K_3	5·47	5·06
Dicoumarol	5 32	4·63
Amytal	0·22	0 00
Amytal + vitamin K_3	5·25	1 04
Amytal + vitamin K_3 + antimycin A	1·57	1·05
Amytal + vitamin K_3 + dicoumarol	1 18	1·48

Each Warburg vessel contained: 10 µmoles glutamate, 20 µmoles *tris* buffer (*p*H 7·4), 20 µmoles orthophosphate (*p*H 7·4), 4 µmoles $MgCl_2$, 2 µmoles adenosine triphosphate, 24 µmoles glucose, an excess of yeast hexokinase, 50 µmoles sucrose, and mitochondria from 200 mgm. liver. The amounts of the additions were as follows: 5 × 10^{-2} µmoles vitamin K_3, 10^{-2} µmoles dicoumarol, 1 0 µmole amytal, 1 µgm. antimycin A, and 1·0 µmole KCN. Final volume, 1·0 ml Temperature, 30° C. Time measured, 20 min. The values for rat are quoted from Conover and Ernster (ref. 6).

Respiration was measured with the conventional Warburg technique. The composition of the reaction mixtures is specified in the table legends. After the manometer readings were completed, the samples were fixed with 0·2 ml. 5 *M* sulphuric acid, and phosphate uptake was determined by the distribution of phosphorus-32, as described by Lindberg and Ernster[12]. Phosphate/oxygen ratio was computed by dividing the number of micromoles inorganic phosphate disappeared by the number of microatoms oxygen consumed. Oxygen consumption for the thermoequilibration period, 5 min., was calculated by direct extrapolation. All chemicals were commercial products; dicoumarol was purchased from AB Ferrosan, Malmo, Sweden.

The absence of DT diaphorase from pigeon-liver could be demonstrated in several ways. In rat-liver, DT diaphorase is most abundant in the cell-sap and

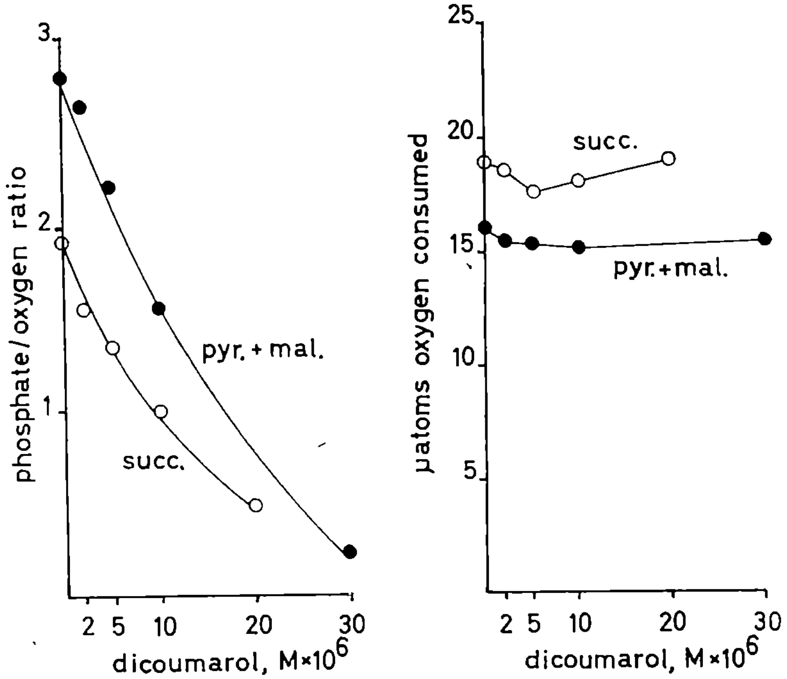

Fig. 1. Uncoupling of oxidative phosphorylation in pigeon-liver mitochondria by dicoumarol. Conditions as in Table 2. The substrates used were succinate or pyruvate + malate

Table 2. RESPIRATION AND PHOSPHATE/OXYGEN RATIOS EXHIBITED BY PIGEON-LIVER MITOCHONDRIA WITH VARIOUS SUBSTRATES

	Substrate											
	Succinate		Pyruvate + L-malate		Citrate		α-Ketoglutarate		L-Glutamate		DL-β-Hydroxybutyrate	
Exp. No.	µatoms oxygen	P/O	µatoms oxygen	P/O	µatoms oxygen	P/O	µatoms oxygen	P/O	µatoms oxygen	P/O	µatoms oxygen	P/O
1	18·0	1·62	16·6	2·80	12·6	2·54	14·4	2·91	12·4	2·88	0·5	—
2	21·6	2·00	12·5	2·42			12 3	2·32	6·7	2·36	0·1	—
3	18·9	1·95	16·7	2·61					14·9	2·08	0·4	—
4	19·5	1·55	17·4	2·51								
5	17·3	2·10							5·1	2·62		

Each Warburg vessel contained mitochondria from 200 mgm. liver, 125 µmoles sucrose, 20 µmoles substrate, 50 µmoles potassium orthophosphate (pH 7·4), 100 µmoles potassium chloride, 16 µmoles magnesium chloride, 2 µmoles adenosine triphosphate, 60 µmoles glucose, and an excess of yeast hexokinase, in a final volume of 2 ml. Temperature, 30° C. Time measured, 20 min.

constitutes the sole diaphorase element of this cell-fraction[5]; consequently, DT diaphorase in this fraction can be simply assayed by measuring the reduction of 2,6-dichlorophenolindophenol by reduced di- or tri-phosphopyridine nucleotide. In the mitochondrial and microsomal fractions, which account only for a minor portion of the total rat-liver DT diaphorase, and in which also other diaphorases are present, DT diaphorase can be demonstrated by measuring the difference in dye-reduction by reduced triphosphopyridine nucleotide in the absence and presence of 10^{-6} *M* dicoumarol[5]. All these tests in the case of pigeon-liver gave completely negative results. A more accurate method for ascertaining the absence of DT diaphorase from pigeon-liver mitochondria was based on the previous finding[6,7] that, in rat-liver mitochondria, addition of vitamin K_3 establishes a by-pass of the amytal-sensitive site of the respiratory chain; this by-pass involves DT diaphorase as indicated by its high sensitivity to dicoumarol (Table 1, left column). With pigeon-liver mitochondria, incubated under identical conditions, no bypass of the amytal-sensitive site of the respiratory chain occurred on the addition of vitamin K_3 (Table 1, right column).

Results from five experiments concerning respiration and phosphate/oxygen ratios of pigeon-liver mitochondria with various substrates are summarized in Table 2. Succinate, pyruvate + malate, citrate and α-ketoglutarate were oxidized at relatively high and consistent rates, whereas the rate of respiration with glutamate varied between medium-high and low from one experiment to another. No respiration under the prevailing conditions was consistently obtained with β-hydroxybutyrate. The phosphate/oxygen ratios ranged between 1·55 and 2·10 with succinate as substrate (average value 1·84) and between 2·08 and 2·91 with pyridine nucleotide-linked substrates (average value 2·50). These values are in perfect agreement with those commonly obtained with mitochondria from rat-liver and other tissues, and fail thus to substantiate the occurrence of a systematic deviation from the normal pattern as suggested by Martius[1]. It may also be mentioned that mitochondria from pigeon-breast muscle which likewise lack vitamin K reductase[9] have been reported by Azzone and Carafoli[13] to exhibit normal phosphate/oxygen ratios.

The absence of DT diaphorase from pigeon-liver mitochondria provided a possibility for deciding the previously raised question[5,7], whether the well-known uncoupling effect of dicoumarol on oxidative phosphorylation[11] is related to its inhibitory effect on DT diaphorase. If this were the case, phosphorylation in pigeon-liver mitochondria should be insensitive to dicoumarol. This proved clearly not to be the case. As illustrated by the results in Fig. 1, dicoumarol uncoupled oxidative phosphorylation in these mitochondria both with succinate and with pyridine nucleotide-linked substrates, and the dependence of the uncoupling effect on the dicoumarol concentration was roughly the same as has been reported[14,15] for rat-liver mitochondria. Furthermore, the half-uncoupling concentration of dicoumarol was the same with succinate and with pyridine nucleotide-linked substrates, about 10^{-5} *M*, which is consistent with the earlier conclusion of Cooper and Lehninger[15] that dicoumarol attacks the three respiratory chain phosphorylations to equal extents.

In summary, the results reported in this article substantiate the previous conclusions that vitamin K reductase is identical with DT diaphorase[5,7], and that this enzyme does not constitute an obligatory link in the aerobic oxidation of pyridine nucleotide-linked substrates in intact, phosphorylating mitochondria[6,7]. It is also evident from the results that dicoumarol can uncouple oxidative phosphorylation in mitochondria lacking DT diaphorase, and consequently, that this effect of dicoumarol very probably is unrelated to its inhibitory effect on DT diaphorase even in those mitochondria in which DT diaphorase is present. This appears to eliminate the possibility, discussed in earlier papers[5,7], that DT diaphorase still might have an accessory function in the coupling of respiration to phosphorylation even though it does not constitute part of the respiratory chain. Hence, the function of DT diaphorase in mitochondria, and in the cell, is still not clear. However, the fact that the enzyme is absent from the pigeon may serve as a valuable basis for future comparative metabolic studies aiming at an elucidation of its physiological function.

X-RAY INACTIVATION OF INDUCIBLE ENZYME SYNTHESIS AND THE EFFECT OF OXYGEN AND GLYCEROL

By Dr. D. L. DEWEY

British Empire Cancer Campaign, Research Unit in Radiobiology,
Mount Vernon Hospital, Northwood, Middlesex

IRRADIATION can not only destroy the reproductive integrity of bacteria and inactivate enzymes, but it can also destroy the ability of bacteria to produce adaptive enzymes. For example, relatively small doses of X-rays could prevent the adaptive formation of formic hydrogenase in *Escherichia coli*[1]. The dose to inactivate the pre-formed enzyme β-galactosidase[2] is about 100 times greater than the dose required to inhibit the adaptive synthesis of the same enzyme[3]. In *Bacterium cadaveris*, Pauly[4] has shown that both the rate of induction and the final adaptive lysine decarboxylase activity formed, fell off exponentially, with increasing X-ray dose. Pauly also found that this effect of X-rays was dependent on oxygen (see Gray[5]). The present article confirms the exponential X-ray inactivation of the inducibility of another adaptive enzyme, concerned in the oxidation of histidine, in a *Pseudomonas*, and demonstrates that both colony-forming ability and the ability to synthesize an adaptive enzyme respond similarly to the modifying agents oxygen and glycerol.

The *Pseudomonas* used in these experiments was isolated from soil and identified as being very similar but not identical to *Ps. ichthyosmia*. The irradiation was 200-kV. X-rays from a Marconi *KX* 10 X-ray tube using a 1·6-mm. aluminium filter and dose-rate between 1,000 and 2,200 r./min. The irradiation vessel was the water-jacketed 'Perspex' vessel used previously[6].

For experiments on cell survival, cultures were grown for 24 hr. at 25° C. in unaerated nutrient broth. Shortly before irradiation the suspension was diluted one in fifty in 0·015 *M* phosphate buffer at *p*H 7. After irradiation samples were suitably diluted in phosphate buffer and plated out in nutrient agar. Visible colony counts were made after 48 hr. incubation at 25° C. The fraction of cells surviving to form a visible colony is shown as a function of dose in Fig. 1.

For experiments on the ability to form the adaptive enzymes concerned with histidine oxidation, the bacteria were incubated with aeration by shaking in a medium consisting of: NaH_2PO_4 5·45 gm.; NaCl 0·9 gm.; $MgSO_4$ 0·1 gm.; NH_4Cl 2·0 gm.; $FeSO_4$ 0·05 gm.; glucose 10 gm.; water to 1 litre, and adjusted to *p*H 7 with 5 *N* potassium hydroxide. Repeated sub-culture on this medium produced poor growth, but by using a cell suspension in 2 ml. of nutrient broth as an inoculum, good growth of unadapted cells was obtained. After 24 hr. incubation at 25° C. the bacteria were centrifuged, washed with water, re-centrifuged and made up in 0·15 *M* phosphate buffer *p*H 7 to a thick suspension containing 10^{10} cells per ml. Portions of this suspension were irradiated in the same manner as for cell survival. 1 ml. of irradiated or control cells was put in each Warburg flask with 1 ml. of 0·15 *M* phosphate buffer *p*H 7, and ½ ml. of 0·04 *M* l-histidine was tipped in from the side bulb. The oxygen consumed was measured at 25° with air in the gas phase.

In preliminary experiments, by using different concentrations of histidine and bacteria, it was found that on addition of inducer the endogenous respiration continued simultaneously and independently of histidine oxidation and was practically unaltered by the doses of radiation used. The endogenous respiration, which amounted to about 6 per cent of the maximum rate of consumption of oxygen by adapted cells, was therefore subtracted from all other readings. The rate of oxygen uptake in excess of endogenous respiration increased slowly after adding histidine. After 7–8 hr. the rate became constant until the histidine was exhausted, when it dropped

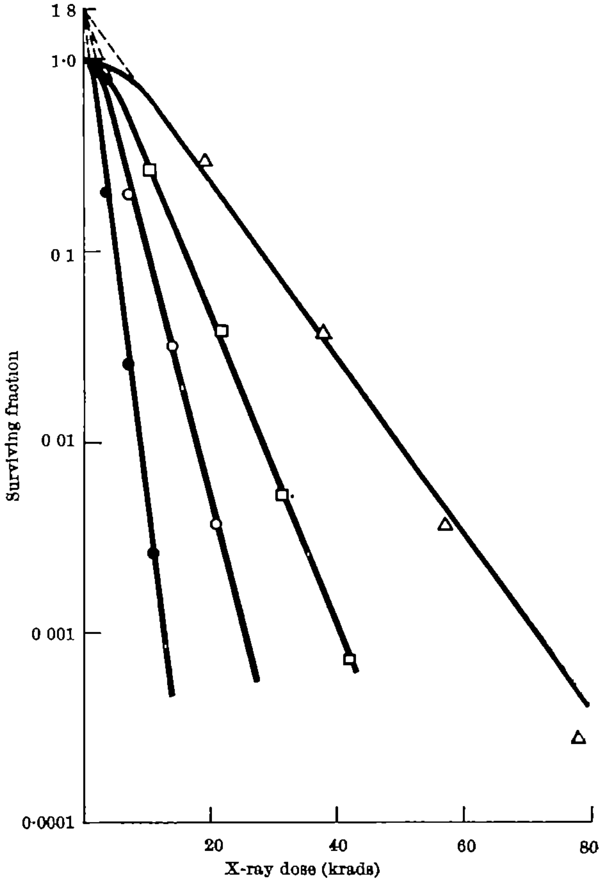

Fig. 1. Loss of colony-forming ability of *Pseudomonas* after 200-kV. X-rays

●, Irradiated in 100 per cent oxygen; ○, irradiated 0·11 per cent oxygen in nitrogen; □, irradiated in nitrogen containing 0 00085 per cent oxygen; △, irradiated in *M* glycerol in nitrogen

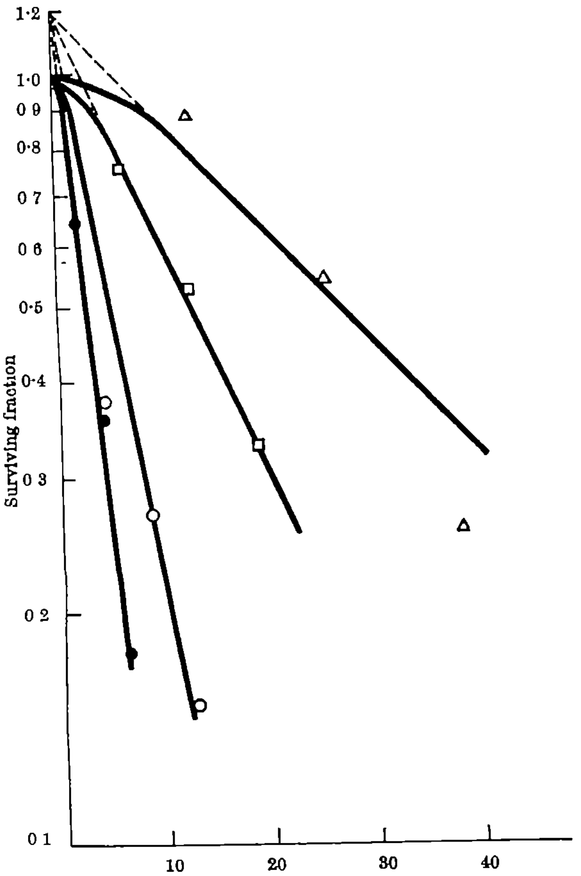

Fig. 2. Loss of ability of *Pseudomonas* to synthesize inducible histidine-oxidizing enzymes. Symbols as for Fig. 1

sharply to a new low value still slightly greater than endogenous. During this time the viable cell count increased by about 25 per cent. The theoretically complete oxidation of each molecule of histidine requires 5 molecules of oxygen. The mean uptake was 50·6 per cent (standard deviation of the mean 0·6 per cent) of the theoretical amount and was independent of histidine concentration in the range measured (2 mM–0·4 mM). The rate of formation of the enzyme was, however, reduced by high histidine concentrations. When cells were irradiated before the addition of histidine the time course of the adaptation process was found to be unaltered, but the fully induced activity was reduced. The drop in this maximum rate of oxygen uptake as a percentage of the controls was used as measure of the X-ray damage.

In Fig. 2 the log fraction of fully induced enzyme activity is plotted against X-ray dose. The scales of Figs. 1 and 2 have been adjusted for easier comparison, and demonstrate that the modifying effect of 0·1 per cent oxygen, nitrogen and *M* glycerol in nitrogen are broadly similar. For a more detailed comparison the slopes of the linear part of the curves measured in krads for a 37 per cent change, are listed in Table 1. The ratio of the 37 per cent doses for colony-forming ability and for loss of adaptive enzyme formation is about 2 in all cases. For the adaptive enzyme measurements, rather high concentrations of bacteria were necessary. When the cell suspension was gassed with 100 per cent oxygen the effects of small changes in oxygen tension are negligible and the exact concentration of dissolved oxygen is not important. When the cells were gassed with nitrogen, respiration helped to maintain anoxia. As a check against possible air leaks, oxygen in the gas emerging from the irradiation vessel was measured by a Hersch cell[7]. Observations were only accepted when the emerging gas contained less oxygen than 20 parts per million. For irradiations at small oxygen concentrations, bacteria were bubbled with gas from a cylinder containing 0·11 per cent oxygen (obtained from the British Oxygen Co.). The difficulty of holding a high concentration of respiring cells at an accurately known low oxygen concentration is considerable[8], and is increased when irradiations are carried out at high dose-rates, on account of the radiochemical utilization of dissolved oxygen[9]. Thus, starting with a suspension in equilibrium with 0·11 per cent oxygen, 10^{10} cells/ml., consuming 10 µl./ml./hr., would render the suspension anoxic in 0·2 min. due to respiration alone, and similarly a dose-rate of 2,000 r./min. would render the suspension anoxic in 0·15 min. due to the radiochemical changes alone. In practice, bacteria at 10^{10}/ml., bubbled with 30 ml./min. of 0·11 per cent oxygen, showed almost anoxic sensitivity when irradiated at 2,000 r./min. Halving both the concentration of bacteria and the dose-rate raised the sensitivity to the level shown in Fig. 2.

Glycerol is known to protect the colony-forming ability of bacteria from X-ray damage. The hyperprotection dose-factor (the amount of protection above the anoxic level) for *M* glycerol was 1·6 compared with 1·9 previously reported for *Serratia marcescens*[10].

Comparable studies of loss of capacity for adaptive enzyme synthesis were complicated in several ways. In the first place, *M* glycerol increases the rate at which *Pseudomonas* becomes adapted to histidine without, however, affecting the maximum level of enzyme synthesis. This is in contrast to the effects of glucose and of excess of histidine, which delayed the adaptive process. The effect of glycerol on the rate of adaptation is not sensitive to radiation. Secondly, in the presence of *M* glycerol the oxygen consumption by *Pseudomonas* is about ten times as great as that due to normal endogenous respiration. Moreover, the additional oxygen consumption, unlike endogenous respiration, is depressed by irradiation, but not apparently to a degree which is related in any simple exponential manner to dose. This effect is therefore difficult to allow for. The points on the glycerol line in Fig. 2 were obtained by subtracting from the rate of oxygen uptake of fully induced cells, the respiration-rate of the same number of cells which had received the same dose of irradiation in the presence of glycerol. Unfortunately, this is a small difference between large numbers with corresponding loss in accuracy. The magnitude of the error is difficult to assess, and although the hyperprotection

Table 1

	Loss of colony-forming ability	Loss of ability to form adaptive enzyme	Ratio enzyme colony
37 per cent dose in oxygen	1·64 krads	3·25 krads	1·98
37 per cent dose in 0·11 per cent oxygen	3·42 krads	5·60 krads	1·64

(O_2), oxygen concentration in solution in µmol./l.; D, 37 per cent dose at the oxygen concentration (O_2); D_n, 37 per cent dose in nitrogen.

of glycerol against X-ray damage to enzyme-inducing capacity is certain, the magnitude of this protection cannot be given with any great precision.

Hitherto, colony-forming ability has been recognized as one of the outstandingly radiosensitive functions of micro-organisms. The observations which are reported here show that, in the case of *Pseudomonas*, the capacity for adaptive enzyme synthesis for histidine oxidation is destroyed by doses which are only about twice as great as those in a comparable loss of colony-forming ability. They show, moreover, that the enhancement of sensitivity by oxygen and the lowering of sensitivity by glycerol is roughly the same for both indices of damage in this micro-organism. Thus, similar radiochemical mechanisms are probably involved in the initiation of both forms of radiation damage. If loss of colony-forming ability is caused by damage to deoxyribonucleic acid (DNA), then a large fraction of this DNA must be left intact if induced enzyme synthesis is to continue. This is supported by the recent finding of Eisenstadt and Novelli[11], who have shown that a cell extract of X-ray inactivated *E. coli* would only synthesize β-galactosidase if specific DNA from induced non-irradiated *E. coli* was added.

From the shape of the survival curves in Figs. 1 and 2 it can be inferred that chemical changes initiated by at most a few ionizing particles are sufficient to destroy the colony-forming ability of a single micro-organism, and the activity of a single centre controlling enzyme synthesis. The question as to whether one or more such control centres are present in each bacterium is at present under investigation.

I thank Dr. L. H. Gray for many suggestions and encouragement.

FACTORS CONCERNED IN THE INITIATION OF GROWTH AND MOULTING IN *LOCUSTA MIGRATORIA* L.

By Dr. K. U. CLARKE and P. LANGLEY

Department of Zoology, University of Nottingham

IN general the life-cycle of an insect is linked to the changes which occur in its environment. Changes in temperature, humidity, photoperiod, and food supply all have their effects on the rates at which processes occur in insects. At extremes, these can lead to a cessation of growth and moulting which may not be resumed until conditions become more favourable, or until some definite stimulus is applied. Thus, in *Rhodnius prolixus* Stal. a blood meal is necessary at the beginning of each instar before further growth and moulting can occur[1], while in *Hyalophora cecropia* (L.) chilling of the pupal brain is necessary before diapause is broken and growth resumed[2]. Both these cases represent adaptations to life in harsh environments. There is, however, no information about the processes which ensure a continuous sequence of moulting cycles in insects which normally feed continuously throughout the greater part of each stadium, and do not encounter conditions liable to interrupt their growth. This article describes those processes which in such an insect, here represented by *Locusta migratoria* L., ensure a continuous succession of growth and moulting cycles throughout its developmental period. Only the conclusions with the main facts which support them are given ; full experimental evidence will be published elsewhere.

An examination of the neuro-endocrine system of the insect was made, using Gomori's chrome hæmatoxylin and phloxine stain for the detection of neurosecretory material. Particular attention was paid to the medial neurosecretory cells, the chiasma formed by their axons, the nervi corporis cardiaci I, and the corpora cardiaca. Studies of the insects made at daily intervals throughout the third, fourth and fifth stadia showed no sign of cyclical changes anywhere throughout the system during this period. Neurosecretory material was found to be present in small amounts in the cell bodies, in their axons, and in the corpora cardiaca, where it was distributed in those regions close to the aorta. This picture is compatible with the continuous active formation and secretion of material throughout the period investigated, and this is taken to be the normal condition in the growing locust. It contrasts markedly with that found in the mature adult, where there is an accumulation of neurosecretory material in the cell bodies, their tracts and corpora cardiaca.

Experiments have shown that the further growth and moulting of the locust was completely stopped by the cutting of the frontal connectives or the removal of the frontal ganglion at any time during the first 50 per cent of the stadium (Fig. 1). Cutting the recurrent nerve behind the frontal ganglion, the outer œsophageal nerve, the ventral nerve cord in front of the first abdominal ganglion, or of only one of the frontal connectives, has no effect over that of control operations on the further growth and moulting of the insects, which proceeds normally.

An examination of the neuro-endocrine system of locusts in which the frontal connectives had been cut, or the frontal ganglion removed 6 hr. after ecdysis to the third instar, was made when they were 211 hr. old. This, compared with operated controls at the end of the third instar, that is 125 hr. after the operation, showed the following points. In the experimental locusts there was a marked accumulation of neurosecretory material in the corpora cardiaca, the nervi corporis cardiaci I (Fig. 2), and the chiasma, but scarcely at all in the protocerebral cells.

The effects of the removal of the frontal ganglion or the cutting of the frontal connectives cannot be attributed to starvation for the following reasons :

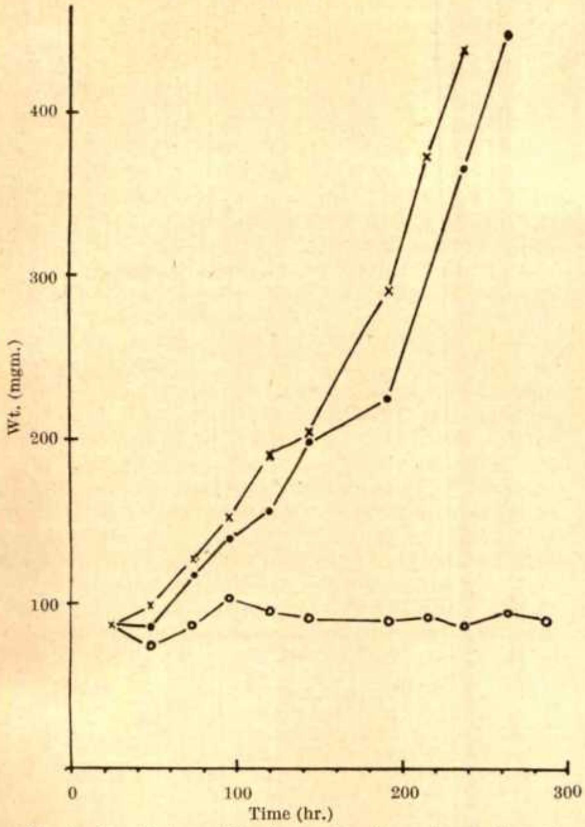

Fig. 1. Growth in weight of normal and experimental locusts throughout the third instar. ×, Unoperated controls; ●, operated controls; ○, with the frontal ganglion removed. The unoperated controls moulted to the fourth instar at 120 hr., the operated controls at 175 hr., those with the frontal ganglion removed did not moult again

the animals were observed to feed regularly, and the gut on dissection was always found to contain freshly eaten grass. The weights of the locusts remained constant at the value they had at the time of the operation ; in starved animals it always fell, or in partially starved animals decreased or increased slowly, but never remained constant. The oxygen consumption of the experimental animals was the same as that of normal insects, that of starved animals was always lower.

Examination of the frontal ganglion both by dissection and in serial sections showed that in addition to the recurrent nerve originating at its posterior boundary and the frontal connectives antero-laterally, there are two pairs of smaller nerves also present. One pair is just in front of the recurrent nerve and the other just behind the frontal connectives. Methylene blue preparations show that these nerves are distributed to the muscles of the pharynx where they end in stretch receptors (Fig. 3). These are placed in line on the pharyngeal wall. No sign of motor endings could be found in connexion with these nerves. (See also ref. 3 for *Oryctes*). Investigations also failed to reveal any signs of neurosecretory cells in the frontal ganglion.

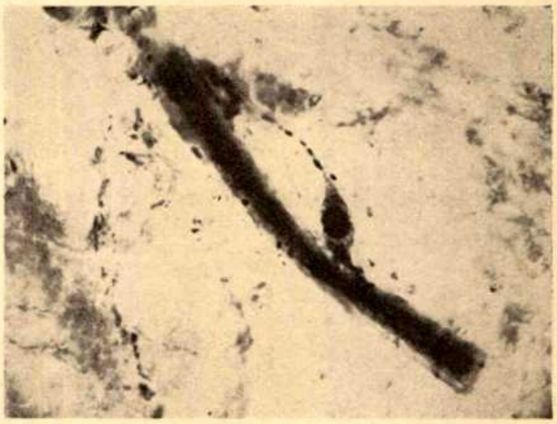

Fig. 3. Photomicrograph of a stretch receptor from the pharyngeal regions of *Locusta migratoria*. Methylene blue preparation

The anatomical arrangements of these parts make it possible for nervous impulses arising from these stretch receptors to pass to the brain via the frontal ganglion and the frontal connectives. It is postulated that in normal circumstances this does in fact happen, and that the continuous activity of the neurosecretory cells depends on the continuous arrival of these impulses. Under normal conditions the impulses arise through the movement of the pharynx. This occurs while feeding throughout a stadium and while swallowing air into the gut throughout ecdysis[4].

Accepting the implications of Thomsen's[5] work on *Calliphora erythrocephala* Meig., that the neurosecretory cells are concerned in protein metabolism, then this mechanism will ensure that the production and release of the hormone is correlated with the intake of food ; a situation similar to that described by Strangeways-Dixon[6] for *Calliphora*. The cutting of the frontal connectives or the removal of the frontal ganglion of the locust causes cessation of the production and/or release of the neurosecretory material (Fig. 2), and hence a cessation of protein metabolism. This would account for the immediate cessation of growth which has been shown to follow from this operation.

The continuous secretion of neurosecretory material poses the problem of how this can produce cyclical moulting in the animal. In the locust one of the first signs of the action of the growth and moulting

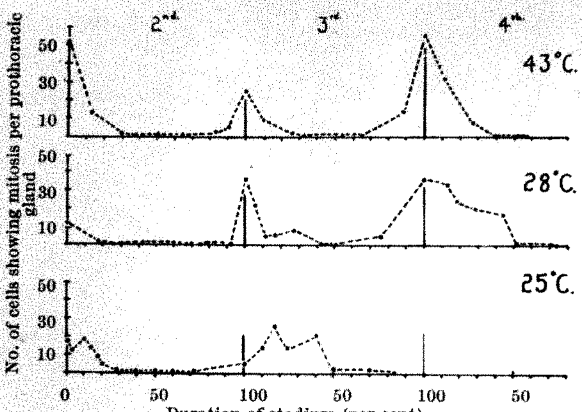

Fig. 4. Graph showing the numbers of mitoses per thoracic gland at different temperatures throughout the second, third and fourth stadia. Each figure represents the mean of at least five glands; during a stadium the low figures are not zero but represent values such as two divisions found in five glands examined

hormone in each cycle is the appearance of mitotic divisions in the cells of the prothoracic gland[7]. Examination of the prothoracic gland throughout the second, third and fourth stadia showed that the peak of frequency of the mitotic figures coincided with the moment of ecdysis (Fig. 4). At temperatures below 26° C. there is a shift of this peak into the following stadium ; but temperatures between 27° C. and 43° C. are without effect on the time of its occurrence. At all temperatures, however, the first appearance of mitotic figures in the prothoracic gland always occurs some hours before ecdysis. The most conspicuous events happening to the locust at about this time are the emptying of the gut of food and the swallowing of air preparatory to ecdysis.

On the basis of the above events the following hypothesis is proposed. That the neurosecretory material is constantly produced and secreted throughout the growth of the locust. During a stadium it is used for the metabolism of proteins associated with the intake of food. At an ecdysis the hormone is still produced but is not used, so that its blood titre will rise. If the prothoracic gland requires a rather higher titre of the hormone than is normally present in the blood, then this is the moment when it will be stimulated. After ecdysis when the animal commences to feed, the titre of neurosecretory material will fall and the prothoracic gland cease to respond. In this manner a cycle of growth and moulting will follow each ecdysis as quickly as environmental circumstances will permit. Thus continuous growth is assured and is independent of any external stimulus being applied at the beginning of each instar.

Since the vast majority of insects are continuous feeders throughout their growth, it is perhaps reasonable to suggest that mechanisms of this sort, which will ensure the fastest possible sequence of moulting cycles, will be widespread throughout the group.

DISTRIBUTION OF THE KANGAROO-TICK *ORNITHODOROS GURNEYI* IN ARID SOUTH AUSTRALIA

By Dr. T. O. BROWNING

Unit of Animal Ecology, Department of Zoology, University of Adelaide

THE kangaroo-tick *Ornithodoros gurneyi*, an Argasid, lives buried in the sand in places where the red kangaroo *Macropus rufus* 'camps' in the shade during the heat of a summer's day.* In South Australia *O. gurneyi* lives a precarious existence, entirely dependent on the behaviour of the kangaroo, in some of the continent's most inhospitable country. A knowledge of how it maintains itself should throw light on more general problems of population ecology in arid regions. For this reason a survey of the tick's distribution was made as a preliminary to a more extensive investigation of its ecology.

Ticks, caught in the field, have been maintained and bred in the laboratory. When fed on rat's blood, adults and nymphs feed fairly rapidly, many completing their feed within 2 hr., but larvæ require three days, on the average, to complete their meal. When fully fed, all stages drop from the host. In the field it is likely that most nymphs and adults, after feeding on kangaroos resting in the shade, would fall back to the place whence they came. But larvæ would be carried for about three days, for the kangaroo is active, and does much of its feeding at night.

From an agricultural point of view, South Australia can be divided into three main regions: farmland, pastoral land, and desert. Fig. 1 shows the 10-in. isohyet of average annual rainfall, which roughly divides the wetter southern region, devoted to farming, and grazing on improved pastures, from the dry pastoral areas where sheep and cattle graze on natural bush 'pasture' on large stations. To the north of this line, the country is either divided into stations or it is virtual desert, uninhabited and ungrazed. Within the pastoral area a wire-mesh, dingo-proof fence, running from the eastern border westwards and then southwards to the Great Australian Bight, separates the southern sheep-country from the dingo-infested northern cattle country (Fig. 1). The boundaries of the pastoral country are also shown in Fig. 1.

The sheep stations are fenced and sub-divided into paddocks, most of which have permanent or semi-permanent water. Many of the cattle stations are unfenced or partly fenced, and waters are often far apart. The whole area is extremely hot in summer, and the low rainfall is unreliable. Droughts of three

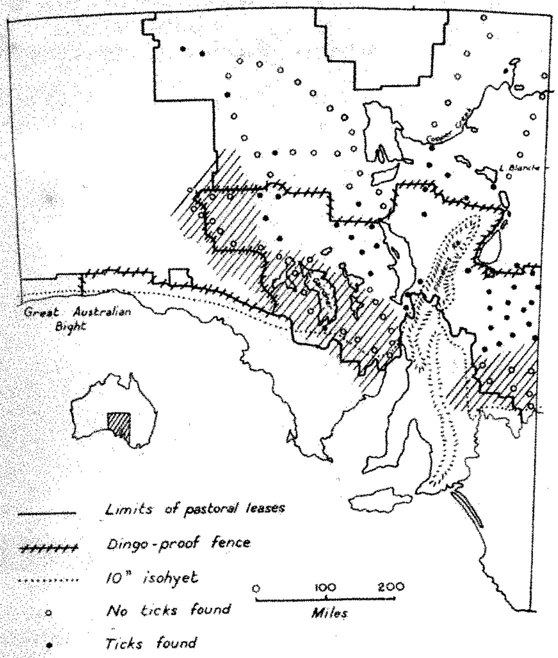

Fig. 1. Showing the places in South Australia in which *Ornithodoros gurneyi* was observed during the survey

or four years duration, with only an inch or so of rain a year, are common.

The vegetation of the station country is very variable, but for present purposes two broad categories can be recognized. Most of the northern areas carry a sparse cover of shrubs and bushes, with trees along the water-courses or in specially favourable situations. In the south and west the land is wooded, carrying dense stands of mulga, *Acacia aneura* and *A. brachystachya*, or myall, *A. sowdenii*, or more open stands of black-oak, *Casuarina cristata*, with bluebush, *Kochia sedifolia*, as an underbrush (hatched area in Fig. 1).

To-day, the red kangaroo does not occur in the farming areas of South Australia, except perhaps as a very rare immigrant, and then the chance of its surviving the farmers' guns must be remote indeed. It is widespread, however, in the pastoral country, despite the fact that the owners of many sheep stations pay a bounty on scalps, and commercial shooting for meat is profitable. The red kangaroo occurs in all the open country south of the dog-fence; but the density of the population varies considerably from place to place. In the timbered areas in the southern and western parts of the sheep country the red kangaroo becomes scarcer as the density of the trees increases. Eventually, as the vegetation becomes scrub, its place is taken by the great grey kangaroo *Macropus major*. On the cattle stations, red kangaroos are scarce as a rule; but local concentrations often occur where food is plentiful. In the area north of the Flinders Ranges as far as Cooper's Creek and west to Lake Blanche, red kangaroos are fairly numerous. They are very rare in the far north-east, but denser in the north-west.

In Fig. 1 are shown all the places in which I have found kangaroo-ticks, and also all the places in which I searched over extensive areas and yet did not find them. The method used in the survey was to drive through the country, stopping frequently and sieving sand from places where I thought a kangaroo might have camped. Ticks were retained in the sieves. Only a very small section of the pastoral area was covered in this way, the search being limited by time and the inaccessible nature of much of the country. Nevertheless, a pattern can be seen in the distribution of ticks shown in Fig. 1.

Ticks were found only in places where there was a resident, though perhaps small, population of kangaroos. The large areas in the north where ticks were not found were places where there were no kangaroos or kangaroos occurred in widely dispersed and shifting groups. But it cannot be said that ticks occur wherever red kangaroos were constantly present, because ticks did not occur in the wooded areas in the southern part of the pastoral country, and yet red kangaroos were more plentiful there than in some of the more open areas where ticks were found. The tick population is confined to the open country and does not penetrate among the trees. The explanation of this, I think, is to be sought in the behaviour of the red kangaroo. In open country, particularly on wide plains where there are few shady bushes, each suitable bush is likely to be used frequently as a camping-place for kangaroos. In such places ticks can almost invariably be found, even when kangaroos are quite scarce. But as the density of suitable camping-places increases, the probability of any one being used at a particular time, decreases, until, when the trees become quite dense, the chance that a tick will get a meal vanishes and a population of *O. gurneyi* cannot persist.

This hypothesis should take into account the density of the kangaroo population; but in the pastoral country kangaroos are unlikely to become sufficiently numerous to enable ticks to survive in thickly wooded areas. There is also a possibility that, even in thickly wooded country, there are places where kangaroos are especially likely to camp. There is some evidence for this. In places where the trees are fairly dense one can often find a broad spreading shrub, throwing a deep shade, where there is evidence that many kangaroos have camped. In such places ticks usually occur. But similar places in thickly wooded country do not show signs of having been used frequently, and ticks do not occur in them.

Yet ticks must frequently be carried in among the trees as larvæ. During the three days they are feeding they are likely to be carried long distances by a large and agile animal like the red kangaroo.

In Fig. 1 ticks are shown in one place south of Lake Gairdner, an area predominantly covered by large myall trees. This one spot represents a few bushes beside a water-course in a large, isolated, treeless area.

This preliminary investigation has posed many problems, some of which it is hoped to take up later. For example, how long can ticks survive in the field and how sparse must the kangaroo population become before ticks are unable to survive, even in treeless country ? How rapidly and over what distances can ticks disperse ? Is there some mechanism whereby larval ticks drop from the kangaroo only when it is camping ? If there is not, the death-rate among larvæ must be extremely high. What keeps the red kangaroo so scarce in large areas of the cattle country ? It may be that dingoes prey on them heavily; but there are extensive areas in South Australia where sizeable populations of red kangaroos exist despite the presence of dingoes. It seems more likely that in the cattle country the kangaroo population is living in much the same way, and at much the same density, as it did before the land was settled, and that the present concentration of red kangaroos on the sheep stations is due to the better supplies of water, and perhaps to the fact that sheep-fences may act as a partial barrier to their dispersal in dry times. This implies that the kangaroo, which is regarded as somewhat of a pest on the sheep stations, is being unwittingly 'farmed' by the graziers.

I thank the Trustees of the Science and Industry Endowment Fund for a grant which helped to defray some of the expenses of this work.

AN INSECT-SPREAD BACTERIAL WILT EPIPHYTOTIC OF BLUGGOE BANANA

By IVAN W. BUDDENHAGEN and T. A. ELSASSER

Plant Pathology Department, Vining C. Dunlap Laboratories, Tela Railroad Co., La Lima, Honduras, Central America

BACTERIAL wilt of bananas (moko disease), caused by a specific race of *Pseudomonas solanacearum*, occurs in various countries of tropical America and has been known since 1910[1]. Its origin on plants of the indigenous musaceous genus *Heliconia* in jungle lands in Costa Rica has been recorded[2]. The disease is distributed, however, in areas where *Heliconia* species are either absent or healthy. Movement on propagating material and spread by tools are well known but do not entirely explain distribution and new outbreaks of the disease[1].

An epiphytotic of moko disease occurred in 1961 in the Ulua valley of Honduras in the bluggoe cooking banana, an *ABB* type[3] known as chato or moroca, that has provided new insight into the disease. The bluggoe cooking banana is planted as a food crop by the farmers and occurs scattered in small patches around houses both in and away from the large commercial Gros Michel banana plantations. Larger plantings exist; these are used for cattle and hog feed. It has been growing at least twenty years in this area unaffected by moko disease until early 1961. When the bluggoe moko disease was brought to our attention in October 1961 it was found that an insect-spread epiphytotic was at its height with the majority of the plants in the valley already diseased. Diseased bluggoes now occur over an area 30 by 10 miles. In contrast to root-infected or tool-infected plants which show symptoms on suckers and leaves, the disease symptoms consisted of blackened and shrivelled flower buds and peduncles. Internally, the fruit of all the fingers of such affected bunches was rotted and blackened. In an area where farmers had noticed diseased fruit 9–12 months previously, symptoms on plants were now systemic. Apparently this area was a primary centre of infection for the subsequent epiphytotic.

Large numbers of bees (*Trigona* sp.), wasps, and other insects normally frequent banana flowers and moist surfaces on the peduncle. Fifty species of insects have been collected from inflorescences from one location and up to 100 bees and wasps per hour have been counted frequenting a single inflorescence. Of 700 bees (*Trigona corvina* Cockerell) and wasps collected in a diseased patch during a 20-day period, 5 per cent were carrying the pathogen as ascertained by direct isolation techniques. Bagging experiments showed that disease did not occur if insects were excluded from the inflorescences.

Bacteria ooze from cushions on diseased peduncles and from bases of bracts in milky white droplets (Fig. 1) for approximately a 10-day period starting about 15 days after infection occurs. Healthy plants are infected when bacteria are carried by insects from such oozing peduncles to moist cushions on the peduncle from which male flowers have recently abscissed. (After the fruit has been produced by the female flowers the bud produces a 'hand' of male flowers each day which absciss at the base of the ovary leaving a 'cushion' on the peduncle of receptacular tissue with the sub-tending bract scar.) A newly exposed cushion can be infected for only about two days after flower abscission; however, the bud exposes approximately one new cushion a day until the fruit is harvested—a period of three months. De-budding experiments have shown that infection does not occur if the bud is broken off before the first cushion of male flowers is exposed.

Once a single infected inflorescence is present in a patch of bluggoe bananas all the hanging inflorescences rapidly become infected. The infection of neighbouring patches is rapid, but distances of more than one mile which are free of bluggoe act as substantial barriers to dissemination. Transmission has occurred, however, in isolated instances to bluggoes as distant as five miles, where secondary centres of the epiphytotic have become established. The

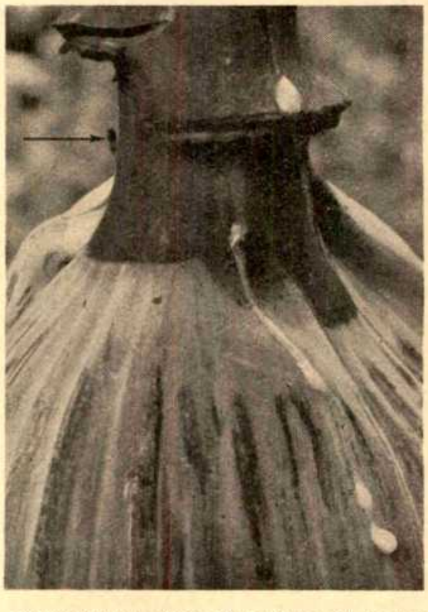

Fig. 1. Diseased bluggoe bud and peduncle with bacterial ooze and insect (arrowed)

agent responsible for long-distance spread is not known, but it may be different from the insects which disseminate locally.

The insect-disseminated pathogen eventually produces typical moko disease symptoms throughout the plant. By invading roots and rhizomes and by dripping from infected buds, it becomes an inhabitant of soils to which it is not indigenous, and may, as a result of tool transmission or root infection, spread to *Heliconia* or other plantains and bananas nearby. Horn plantain (*AAB*) is usually healthy even when growing adjacent to bluggoe patches which are completely diseased, since the male axis on this variety degenerates early, precluding bud infection. However, in the oldest infected bluggoe areas horn plantains are becoming diseased following root infection or pruning tool transmission.

Inoculum present in bluggoe patches has been carried by insects to commercial banana plantations and sporadic cases have appeared in many farms of Gros Michel that have never before had moko disease. In some instances undetected inflorescence-infected Gros Michel plants have become sources for subsequent spread on pruning tools. Previously, such appearances of the disease in new areas could not be explained. The practice in commercial banana production in Central America of removing the buds from the male axis has by coincidence greatly reduced chances of dissemination of the disease via insects. We believe there are other as yet undetermined factors which contribute to the reduced incidence of inflorescence infection of commercial bananas.

The strain of the banana race of *P. solanacearum* which is causing the bluggoe epiphytotic is distinguishable on the basis of colony morphology from another banana strain that has caused most of the moko disease in commercial bananas in the Ulua Valley for the past six years, and from the banana strain that causes moko disease in other parts of Central America. It is thus possible to determine if new disease cases in commercial banana farms are related to the insect spread epiphytotic in bluggoe bananas.

The senior author recently visited Colombia where, in the Department of Tolima along the Magdalena River, moko disease of bluggoe (there known as cachaco) occurs. The disease situation is similar to the epiphytotic in Honduras. During the past one to two years spread by insects has occurred over a distance of 60 miles from a small disease source known to have existed for about five years. In Venezuela, the disease also occurs on bluggoe and on other varieties in areas around Lake Valencia where the pathogen is not indigenous since *Heliconia* species are not present. It is suggested that the disease there also is insect spread and has been disseminated from more humid lowland areas via the bluggoe flower-infection chain.

After having seen the epiphytotic on bluggoe in Honduras it is now possible to understand the earliest reports of moko disease from Trinidad, which state that around the turn of the century the moko (bluggoe) plantain was virtually wiped out on the island whereas other varieties, although susceptible, were only occasionally diseased. What undoubtedly occurred was an insect-disseminated epiphytotic in this variety.

We are now able to propose a hypothesis which covers many aspects of the biology of this disease. (1) It has evolved on *Heliconia* in certain specific areas of the jungles of tropical Central and South America, where some of the strains are sufficiently *Musa*-adapted to infect bananas or plantains via the roots. (2) The disease in bananas spreads slowly via root infection, more rapidly via contaminated tools and to new areas on diseased rhizomes. (3) In commercial banana plantations insects occasionally transmit the bacteria from diseased inflorescences or from cut surfaces to healthy inflorescences, sometimes at a distance. (4) Once the disease reaches bluggoe, insects initiate infection cycles which rapidly move the pathogen into new areas, into higher and drier soils where *Heliconia* do not occur. (5) The bluggoe moko disease begins initially as an epiphytotic, later subsides, and becomes endemic in the survivors.

We suspect that originally, in the jungle, spread among *Heliconia* species may also have been occurring through flower infection, and that epiphytotics in *Heliconia* may have occurred in this manner from more localized centres of origin. Although we have no proof for this hypothesis, we have been able to infect *H. latispatha* by spraying bacteria on to the inflorescence.

It may be expected that moko disease can eventually appear in any warm area of tropical America where there is a continuous chain of plantings of bluggoe cooking bananas back to wet lowlands that have *Heliconia* species diseased with the banana strain of *P. solanacearum*. It is interesting that although bluggoe is a significant food source in many areas outside America—Philippines, South India, East Africa and elsewhere[3]—no report of moko disease has appeared from those areas, nor is *Heliconia* indigenous to them.

METABOLIC REGULATION OF THE ALKALINE EFFECT OF NITRATE UTILIZATION IN PLANTS

By Dr. W. DIJKSHOORN
Institute for Biological and Chemical Research on Field Crops and Herbage,
Wageningen, Holland

IN earlier investigations a practically complete survey of the ion equivalents involved in uptake by *Lolium perenne* L. was obtained[1–5]. A subdivision was also made as to form of chemical combination of nitrogen[4], sulphur[6] and phosphorus[7] in order to throw light on utilization and requirements for normal growth.

In the present article the regulation of the electroneutrality is considered more in detail. The ion balance of uptake showed that at adequate supply with nitrogen after four weeks re-growth, total cation absorption was about 1·8 equiv. K + Na + Mg + Ca and total anion absorption about 3·2 equiv. $NO_3 + Cl + H_2PO_4 + SO_4$ per kgm. dry matter produced[4,8].

It follows from electroneutrality that the deficit of neutral cations: $3 \cdot 2 - 1 \cdot 8 = 1 \cdot 4$, is an apparent uptake of acid H^+ ions. If grown on an initially neutral salt solution, which is partially exhausted at the completion of the uptake, an excess of 1·4 equiv. of the neutral cations supplied would remain in the solution for each kgm. dry plant matter produced. This excess is now balanced by OH^-, the former partner ion of the H^+ withdrawn by the uptake.

Consequently, the apparent H^+ uptake remains behind in the solution as its equivalent of the strongly basic hydroxides of the cations supplied. This is the external alkaline effect, and the conditions for its occurrence will be dealt with after discussion of the internal balance of uptake and utilization.

The apparent H^+ uptake is large relative to the total uptake and weight of the plant and should result in a pronounced internal acidification. Since the titratable acidity of the plant material is very small, it appears that the apparent H^+ uptake is only a numerical quantity in the balance of uptake which is neutralized as it is absorbed. Although the *p*H of the plant sap is favourable for the buffer action of a number of constituents their internal concentration is usually so low that this must become overshadowed by some other process which eliminates the internal acidity due to the uptake.

The ionic equations:

$$(N^{5+}O_3)^- + 8H^+ + 8e \longrightarrow (N^{3-}H_3) + 2H_2O + OH^-$$

and

$$(S^{6+}O_4)^{=} + 8H^+ + 8e \longrightarrow (S^{2-}H_2) + 2H_2O + 2OH^-$$

show that the reductive assimilation of the non-basic nitrate and sulphate anions transfers their ionic charges to strongly basic OH^- anions.

Kjeldahl nitrogen was found to be equivalent to 2·7 nitrate equivalents and unchanged nitrate was present at 0·45 equiv./kgm. dry matter. Since nitrate participates in some 60 per cent in the Kjeldahl modification used, it must have been assimilated at a rate of about 2·4 equiv./kgm. dry matter. From other evidence[6] it follows that sulphate assimilation must have been near to $0 \cdot 06 \times 2 \cdot 4 = 0 \cdot 14$ equiv./kgm. dry matter.

This shows that the conversion of nitrate and sulphate to the non-ionic organic form issues as about 2·5 equiv. alkali/kgm. dry matter. This total internal alkali (a_t) due to the balance of utilization is considerably in excess of the apparent H^+ uptake or external alkaline effect derived from the balance of uptake. Hence, the complete balance of uptake and utilization can easily account for the absence of internal acidity.

A considerable portion of the total internal alkali (a_t) becomes neutralized by the external alkaline effect (a_e) or apparent H^+ uptake. The remainder is called here the internal alkalinity $a_i = a_t - a_e$. It originates from the reductive assimilation of nitrate and sulphate anions which, together with the other ions, have been absorbed as the nitrates and sulphates of potassium, sodium, magnesium and calcium, the neutral cations supplied, and should be present in the plant as the corresponding hydroxides.

In the numerical example given here the internal alkalinity $a_i = 2 \cdot 5 - 1 \cdot 4 = 1 \cdot 1$ equiv./kgm. dry matter. In spite of this high value the plant material does not show excess titratable alkali. Apparently a_i is a numerical value of the balance of uptake and utilization which is neutralized by the metabolism as soon as it is formed.

There is every reason for relating this directly to the metabolic synthesis of organic acid molecules. The naturally occurring plant acids (malic, citric, oxalic, etc.) are sufficiently strong (*p*K's 1·5–5·5) to exist almost wholly as their salts at the *p*H of the plant sap. We have only to test whether organic acid production proceeds at a rate comparable with the internal alkalinity derived from the balance of uptake and utilization.

For this purpose I have made a few analyses on organic acids in *Lolium perenne* grown under similar conditions as before. Fresh herbage samples, corresponding to 2·25 gm. dry matter, were repeatedly extracted with a total of 500 ml. boiling water, the extracts decationized and passed over an anion exchanger (strongly basic, OH^-). Elution of the acids other than oxalic was effected with 5 *N* formic acid and, after evaporation to dryness *in vacuo*, they were submitted to partition chromatography on silica gel according to modified prescriptions of Bulen, Varner and Burrel[9]. Oxalic acid was recovered by a second elution of the exchange column with 1 *N* sulphuric acid and determined by direct titration of the eluate with permanganate. A total of about 2·2 m.equiv. organic acids was developed off the partition column and 0·13 m.equiv. oxalic acid was obtained. Recalculation yields a value of about 1 equiv. of non-volatile organic acids/kgm. dry matter, which is very near to the above value for a_i.

Let us now consider the external alkaline effect in more detail. It results from the fact that the neutral anions supplied are absorbed in excess of the neutral cations supplied and is formally explained by the uptake of H^+ equivalent to the deficit of neutral cations absorbed. The water of the solution is a practically inexhaustible source of H^+, but its actual concentration is usually very low relative to the salt concentration. However, the external alkaline effect should not necessarily be connected with a true uptake of H^+. The internal alkali produced in excess might as well undergo an overall distribution in the plants and neutralize the acidity during its entrance in the root system. This brings us close to the view put forward earlier that instead of H^+ uptake there is a release of OH^- to the external solution in an amount equivalent to the excess of neutral anions absorbed[4], which passes into the plant merely by exchange. This view implies an external neutralization of the apparent H^+ uptake instead of its internal neutralization in the case of true H^+ uptake. Of course, the question as to whether or not uptake of H^+ occurs is not of practical interest because entrance of H^+ means numerically the same as the release of its equivalent OH^-.

In the absence of nitrate utilization by the metabolism the external alkaline effect fails to reach a level of significance because the acidity of the uptake remains unneutralized. So far as normal growth is concerned a continuous utilization of the nitrate absorbed is a condition to the progress of the external alkaline effect. The foregoing reasoning shows that it is also associated with sulphate utilization. The small partial effect thereof remains unrecognized because sulphate assimilation proceeds only together with the far more prominent nitrate assimilation[6].

The foregoing balance shows that the internal alkalinity, which is the total internal alkali not neutralized by the external alkaline effect, becomes completely neutralized by the synthesis of organic acid molecules. If in healthy growing neutral plants the permissible loading with excess internal acidity (H^+, H_3O^+ and other acidic cations as NH_4^+) would be low (for example, < 0·1 equiv./kgm. dry matter) any organic acid production in excess of the internal alkalinity cannot take place without disturbing growth, uptake and utilization by too excessive internal acidification. The response would be an increase in the uptake of neutral cations so as to reduce the acidity of the uptake or external alkaline effect. A too low production of organic acids would result in an accumulation of internal alkalinity (OH^-, HCO_3^- and other basic anions) beyond the permissible loading. The response would be a decrease in the uptake of neutral cations in order to augment the acidity of the uptake and external alkaline effect.

Thus the complete balance of uptake and utilization is essentially composed of and determined by the reciprocal actions of cation uptake, anion uptake, reductive utilization of nitrate and sulphate and synthesis of organic acids. A discussion whether each term has or has not an independent existence is beside the point since it cannot vary apart from the others and is bound up with the particular conditions of growth and uptake.

According to our present routine the balance is obtained by plant analysis on the cations $C = K + Na + Mg + Ca$ and the anions $A = Cl + P + S + N$, expressed as equiv./kgm. dry matter of the ionic forms supplied. In plants grown in soil other elements do not usually add to the uptake of equivalents in significant amounts. Silica is absorbed by grass up to a marked weight percentage, but due to the very weak acidic properties of silicic acid and its probably polymerized state its contribution seems negligible in the balance of equivalents. In addition, unchanged nitrate is determined. Its recovery as ammonia in the Kjeldahl procedure for total nitrogen should be known, or otherwise special precautions are taken for its complete recovery. In the normal case of nitrate supply assimilated nitrate (N_0) is obtained by subtracting nitrate from total nitrogen. Assimilated sulphate (S_0) is calculated as above. Calculation yields: the external alkaline effect $a_e = A - C$; the total internal alkali production $a_t = N_0 + S_0$; the internal alkalinity $a_i = a_t - a_e = N_0 + S_0 - A + C = C - A_i$ in which $A_i = Cl + \text{total } P + $ inorganic sulphate + inorganic nitrate, the anions still present in the form in which they have been absorbed. It is assumed that the ionic state of phosphorus is not changed by its utilization.

In neutral plants $C - A_i$, the excess of neutral cations to unchanged neutral anions should be present as the salts of organic acids. This has been demonstrated for a number of plant species (with a single exception) by Pierce and Appleman[10]. Their values for $C - A_i$ are somewhat too low, which might have been caused by the use of total sulphur values instead of sulphate, in view of the probably high nutritional status of the plants.

ASYMMETRICAL RIPPLE MARKS AND THE ORIGIN OF CROSS-STRATIFICATION

By J. R. L. ALLEN

Sedimentology Research Laboratory, Department of Geology, University of Reading

A CLEARER understanding and more satisfactory classification than hitherto of asymmetrical ripple marks formed in water has resulted from a previously unattempted quantitative morphological analysis of small current ripples and asymmetrical 'sand-waves', using published and unpublished data. The work, which will be reported later in full, has revealed for the first time in three-dimensional detail some part of the geological role these structures may have had in forming cross-stratification generally. Sorby[1] and Hülsemann[2] had previously shown the clear connexion between asymmetrical ripple marks and cross-stratification, but only in terms of two-dimensional vertical sections parallel to the current direction.

Asymmetrical ripple marks are features of loose grain beds, migrating down-current in societies by addition of sand in layers to the steep or lee-sides as erosion proceeds to varying degrees depending on sediment supply on the gentle or stoss-sides. The proposed new classification is based on their form and scale, and is primarily morphological (Table 1).

Table 1. CLASSIFICATION AND NOMENCLATURE OF ASYMMETRICAL RIPPLE MARKS

I. *Straight forms*	
(1) Straight small-scale ripple marks	Form-drag conditions
(2) Straight major ripple marks	Conditions other than form-drag
(3) Straight megaripples	
II. *Linguoid forms*	
(1) Linguoid small-scale ripple marks	Form-drag conditions
(2) Linguoid major ripple marks	Conditions other than form-drag
(3) Linguoid megaripples	
III. *Lunate forms*	
(1) Lunate major ripple marks	Conditions other than form-drag
(2) Lunate megaripples	

Three forms of asymmetrical ripple mark have been distinguished on the appearance of the crests in plan. The straight forms have essentially straight crests which lie parallel to each other in a society of ripples. The crest lines of the linguoid forms are generally strongly curved, turning through almost 180°, with closure always in the down-current sense in an assemblage. In the lunate forms, which resemble æolian barchans, the crests are also strongly curved, the closure being consistently up-current in a society.

Asymmetrical ripple marks have been found to occur within two apparently discrete size ranges. The straight and linguoid forms of small scale, the familiar current ripples of beaches and streams[3], have crest heights generally less than 3 cm. It has been found that the wave-length/height ratio decreases with increasing scale, as do all linear measures with diminishing grain size. No relation has been detected between ripple-height and water-depth.

The large-scale structures, among which the height varied from 5 cm. to 22·5 m., have been classed either as major ripple marks or megaripples, the distinction being made arbitrarily within the continuous variation of linear measures at a ripple height of 1 m. Straight forms at this scale are abundant in many shallow seas[4-6], rivers[7-9] and estuaries[3,10]. Van Straaten[11] has reported linguoid forms from ebb-flood channels, and they are known to occur as well in rivers like the Benue, Nigeria. Lunate structures of carbonate sand occur on certain submerged rock platforms of the Bahamas[5,12]. It has been found that among straight major ripple marks and megaripples the wave-length/height ratio increases with growing scale, in contrast with the small-scale forms. No relation was detected between grain size and scale. From an analysis of echograms and other depth profiles, the height of the ripple crests has been found to depend closely on the depth of the overlying water. The empirical logarithmic relation expressing this is:

$$D = 0{\cdot}8901 + 0{\cdot}8271H$$

where D is mean water depth (m.); H is mean ripple height (m.), the number of observations being 38, the correlation coefficient 0·91, the standard error of estimate 0·20, and the range of H from 0·075 to 7·80 m. The relation is based on data from the North Sea and British estuaries, and the Rivers Mississippi, Benue, Klaralven (Sweden) and Hii (Japan). The reason for expressing the relation as the regression of depth on height is explained here.

Small-scale asymmetrical ripple marks thus differ from the large-scale in the relation of: (1) wave-length/height ratio to linear scale; (2) linear scale to grain-size; (3) height to water-depth, in addition to being apparently discrete in size-range.

These morphological differences suggest a genetic distinction, some confirmation of which comes from Bagnold's[13] theoretical work. Bagnold showed that the structures classed above as small scale arose on a grain bed to provide between two critical flow intensities a certain 'form-drag' sufficient to balance a deficit in favour of the fluid between shearing transmitted from the flow and shearing resistance generated by grain encounters at the bed. The large-scale kinds, referred to as 'dunes', he suggested to form under a wider range of conditions of the whole flow, whenever suitable interaction occurred between a fluctuating current and an irregular bed. The relation between ripple-height and water-depth appears to substantiate Bagnold's prediction that their scale should depend on some major property of the entire flow. In the above light, the genetic significance of the different asymmetrical ripple marks has been noted in Table 1.

Numerous earlier investigations showed that ordinarily both small- and large-scale asymmetrical ripple marks shift down-current through simultaneous stoss-erosion and lee-deposition. Bearing in mind this unique mode of translation, it can be demonstrated using models how the three-dimensional internal structure of a deposit permanently left by a group of ripples will depend on the geometry of the moving bed. Demonstrations of this kind seem important in correctly understanding cross-stratification.

Fig. 1*A* represents an assemblage of straight ripple marks assumed to be moving under conditions of sediment supply allowing both permanent accretion beneath the rippled surface and stoss-erosion on the ripples. The effect on the sediment being built up of this moving pattern of parallel areas of erosion and deposition oppositely inclined is the structure in Fig. 1*B*. This consists of tabular layers of foresets deposited on the lee-sides of the ripples as they advanced, bounded by plane erosional surfaces swept out by the stoss-sides. Unless stoss-erosion was extreme, the thickness of each layer will compare with the height of the parent ripple, this depending on water depth for instances of large scale.

A structure identical with that deduced is familiar in the geological record[14] as planar cross-lamination, when the layers of foresets are a few cm. in thickness, and as planar cross-bedding when thicknesses measure decimetres or metres. Its essential features are, as in the model, plane erosional surfaces between successive layers, and foresets dipping consistently in the same general direction through each set of layers. Ancient sands marked by planar cross-stratification may thus have been deposited from societies of straight asymmetrical ripple marks. Wright's[15] explanation of the structure is unacceptable, since of the many modern point-bars examined none were found to have the characters he assumed The concepts underlying the formation of planar cross-bedding as explained experimentally by Sorby[1]

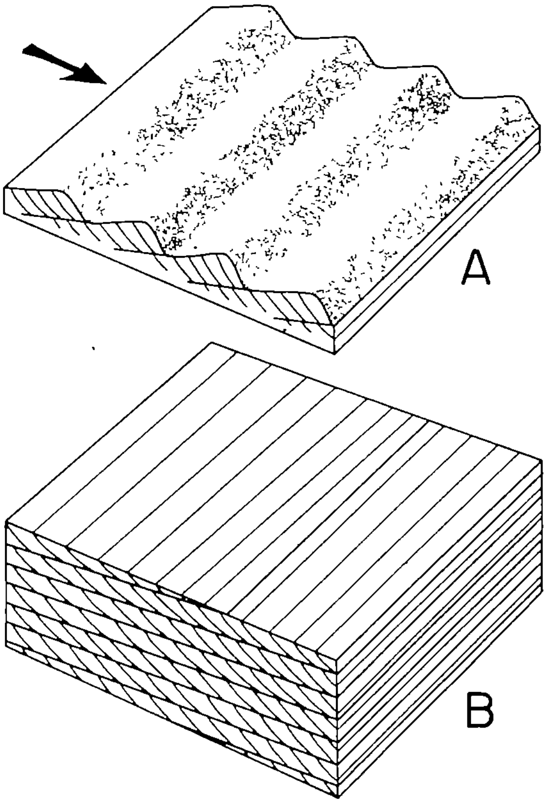

Fig. 1. Formation of planar cross-stratification from straight asymmetrical ripple marks. Arrow shows current. Erosion surfaces shown as thick lines, foreset planes as thin

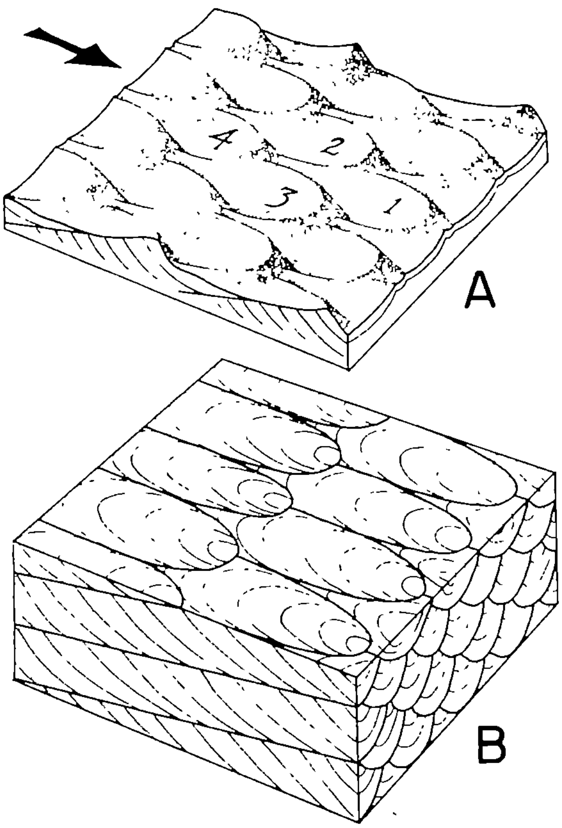

Fig. 2. Formation of trough cross-stratification from linguoid asymmetrical ripple marks. Arrow shows current. Erosion surfaces shown as thick lines, foreset planes as thin. Troughs of lower diagram slightly vertically exaggerated relative to ripples of upper one

and McKee[16] are difficult to accept in view of the behaviour of ripple marks.

In the above light the thickness of planar cross-bedding assumes importance as a guide to depth of deposition. Measurements of median thickness suggest, using the empirical relation above between ripple-height (cross-bed thickness) and water depth, the inter-tidal origin of the Lower Calcareous Grit of Berkshire (median, 12·5 cm.), sub-tidal to deeper sedimentation of the Folkestone Beds around Farnham, Surrey (median, 59 cm.; locally sets with median about 3 m.), in an environment perhaps resembling that of the southern part of the North Sea, and deposition from shallow streams for the Ditton Series of Shropshire (median, 19 cm.). Substantial rivers are implied by data from the Rough Rock[17].

Fig. 2*A* represents a society of linguoid asymmetrical ripple marks under the conditions assumed above. The arrangement of erosional and depositional areas is in this case more complex, the erosional ones being hollows crescentic in plan and distributed *en echelon*. The formation by this pattern of an internal structure in a sediment is most easily understood by considering the behaviour of the unit of four adjacent ripple marks distinguished in Fig. 2.

As ripple 1 advances its concave-upward stoss-side will sweep out erosively a concave trough-like surface. As speedily as this surface is eroded there will be deposited on it concave-upward foreset layers formed jointly on the advancing right-hand lee of ripple 2 and left-hand lee of ripple 3, the layers moulding themselves to the trough floor and dipping symmetrically inward toward its axis. The advancing stoss-sides of ripples 2 and 3 will partly truncate these layers and the upturned edges of the initial trough. Final truncation will occur as the stoss of ripple 4 advances over them. The resulting structure will thus comprise a long erosional trough filled with concave foresets bounded by similar erosional troughs. When all the ripples of the assemblage behave mutually in this way, the final structure is that shown in Fig. 2*B*.

An identical structure to this is widely known in the geological record[14] on the small scale as trough cross-lamination and on the large scale as trough cross-bedding. All the essential features of the model are reproduced, as shown by work on examples of both scales in the Lower Old Red Sandstone. Trough cross-stratification may therefore have arisen in the past from migrating societies of linguoid asymmetrical ripple marks.

This structure was formerly interpreted by Knight[18] and Sutton and Watson[19] as the result of channel cutting and then filling. Hamblin[20] correctly recognized that a relation existed between small-scale linguoid ripple marks and trough cross-lamination, but did not explain it.

Wurster[21] and Niehoff[22] accounted for trough cross-stratification by deposition from underwater 'barchan' ripples or dunes. The present circumstances of known underwater lunate ripple marks[5,12], which are very rare compared with straight-crested varieties in the same environment, suggests that they would not have formed permanent deposits. Like many æolian barchans, they are known only as isolated mounds on rock platforms where sand is in poor supply, becoming transformed into straight-crested ripples where supplies increase enough to cover the platforms entirely[5]. Were cross-stratified units ever to form from lunate ripples, it seems possible that they would be bounded by convex-upward surfaces.

Future work with models should reveal details of the cross-stratification patterns formed from asymmetrical ripple marks under other, more extreme, conditions of sediment supply.

I thank Prof. P. Allen for criticizing this article, Mr. R. G. C. Bathurst and the Directors of Netherlands Engineering Consultants for supplying data, and Dr. R. N. Curnow for aid with the statistical work.

LETTERS TO THE EDITOR

RADIOASTRONOMY

Millimetre-Wave Radio Source in Taurus

RECENT microwave observations by Kuzmin and Salomonovich[1] and by myself of the radio emission from Taurus have revealed the presence of an unusual radio source located approximately 9 min. of arc east of Taurus-*A*. Kuzmin and Salomonovich observed the source with the 22-m. radiotelescope of the Lebedev Institute of Physics operating at 8-mm. wave-length and with a pencil beam-width of 2 min. of arc to the half-power points. While taking drift curves on Taurus-*A*, these workers detected a new source approximately 35^s east of Taurus-*A*. The reported flux density at 8-mm. wave-length is $1{\cdot}30 \times 10^{-24} \pm 25$ per cent W./m.^{2} (c.p.s.), the brightness temperature, T_B, is 7 ± 25 per cent ° K., the angular width in right ascension is 2·5 min. of arc and the flux density ratio to Taurus-*A* is 0·26. Kuzmin and Salomonovich conclude that the source is a thermal emitter with an emission measure of $2{\cdot}7 \times 10^6$, as would certainly be expected from a source initially discovered at 8-mm. wave-length.

The purpose of this communication is to point out that Kuzmin and Salomonovich's interpretation is inconsistent with the observations reported by Barrett at 1·8-cm. wave-length; however, it should be noted that the 1·8-cm. results were not available to Kuzmin and Salomonovich at the time. I have observed several strong radio sources with a 26-m. radiotelescope operating at 1·8-cm. wave-length with a 3·0 min. of arc pencil beam-width. In these observations of Taurus-*A* (Fig. 1), which included the region of the new source, no evidence of the source was detected, thereby enabling the establishment of an upper limit on the flux density of 0·05 times that from Taurus-*A* at 1·8-cm. wave-length. This upper limit, corrected for the finite source, size, and beam-width, is represented by the dotted curve of Fig. 1.

By assuming that the source is thermal, and using Kuzmin and Salomonovich's data, it can readily be shown that the optical depth of the source at 8-mm. wave-length is approximately 6×10^{-4}, and hence the optical depth at 1·8-cm. wave-length should be approximately 3×10^{-3}. Therefore, the source should be optically thin at both wave-lengths. If this were the case, the dashed curve of Fig. 1 would have been recorded. The observations clearly exclude this possibility. Indeed, observations at 3-cm. and 3·2-cm. wave-lengths, some of which were made by Kuzmin and Salomonovich, are not consistent with the interpretation of a thermal, optically thin source, since they should have revealed the source[3,4]. On the other hand, a comparison of the two results with Taurus-*A*, after correcting for the spectrum of Taurus-*A* and assuming a spectral index of $-0{\cdot}28$ (ref. 5), shows that the flux density of this new source at 1·8-cm. wave-length is no greater than one-fourth that at 8-mm. wave-length. Therefore, if the source is a thermal emitter, it must be interpreted as being one having an optical depth greater than unity at both 1·8-cm. and 8-mm. wave-lengths. This conclusion was pointed out by me[2]. To match the observed flux densities and still retain the concept of a thermal source requires optical depths of approximately 8·7 and 1·7 at 1·8 cm. and 8 mm., respectively, and leads to the absurd value of 8·5° K. for the electron temperature to give Kuzmin and Salomonovich's observed brightness temperature. We conclude that this source is not thermal, in the usual sense, if the observations are to be accepted.

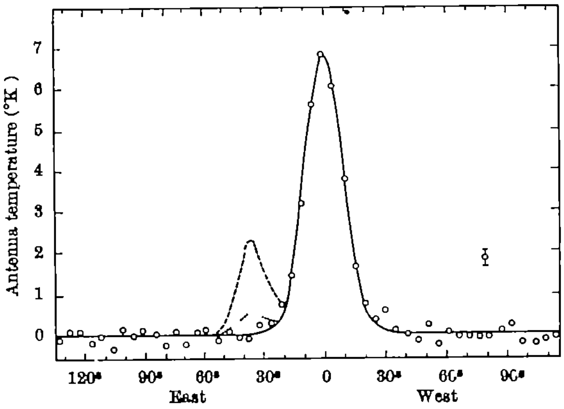

Fig. 1. Observations of Taurus-*A* at 1·8-cm. wave-length (solid curve). The dashed curve represents the result to be expected for the new source if it is thermal and optically thin; the dotted curve is the upper limit set by the 1·8-cm. observations

An interpretation of this source in terms of synchrotron radiation leads to a most unusual energy spectrum for the radiation electrons. Again, taking the spectral index of Taurus-*A* as $-0{\cdot}28$, it follows that the spectrum of the new source is at least as steep as $S \sim \lambda^{-1{\cdot}8}$. Since the flux-density spectrum from a distribution of relativistic electrons is given by $S \sim \lambda^{\frac{1-\gamma}{2}}$, where γ is the exponent defining the electron energy distribution, the observations imply an energy distribution of the form $N(E)\,\mathrm{d}E = \mathrm{k}E^{2{\cdot}6}\,\mathrm{d}E$, which is equally as unacceptable as the low value of the electron temperature indicated above.

Kuzmin and Salomonovich report an angular width in right ascension of 2·5 min. of arc from their preliminary observations, but this is sufficiently close to their minimum resolution of 2 min. of arc that I feel it does not rule out the possibility that the source is actually much smaller than this. An anomalously high first side lobe of their antenna pattern might reproduce their observed results, but this possibility seems to be excluded by their direct pattern measurements and their observations of Venus[6,7]. Therefore, if Kuzmin and Salomonovich's observations are valid, I conclude that this source is of a type that has not been encountered before in radioastronomy and that further measurements at short centimetre and millimetre wave-lengths are urgently required to confirm the existing observations and to extend the spectrum.

It should be pointed out that in this discussion I have used the values quoted by Kuzmin and Salomonovich. In particular, the brightness temperature of 7° K. obtained by them was derived from the Rayleigh–Jeans approximation to the Planck radiation law. However, it can easily be shown that for 8-mm wave-length and $T_B = 7°$ K. the requirement that $h\nu/kT \ll 1$ is not satisfied and values derived from the Rayleigh–Jeans law must be corrected approximately 11 per cent. This is less than their stated uncertainty, and I have ignored this correction because it does not alter the results; however, I believe that this is the first time the correction has assumed significant proportions in radioastronomy, and it is obvious that as the science of mm.-wave radioastronomy progresses the Rayleigh–Jeans approximation must be used with caution.

The programme of research in radioastronomy at Massachusetts Institute of Technology is supported in part by the U.S. Army Signal Corps, the Air Force Office of Scientific Research, and the Office of Naval Research.

Interpretation of 'Surface Brightness' Measurements of Radio Sources

It is now recognized that most of the observed radio sources are extragalactic objects with radio powers greater than that of the Galaxy. It is, however, impossible to measure the distance of an individual source directly from radio observations alone, so that apart from the few sources for which optical red-shifts are available estimates of the radio luminosity function have had to be made by indirect means.

Some authors[1,2] have made observations of the radio surface brightness, and their results have been used to estimate the radio luminosity function assuming a typical linear dimension for the sources. Such discussions have not usually taken account of the change in the apparent surface brightness of a source with distance[3,4]. It is the purpose of this communication to direct attention to the fact that if this effect were considered, then for some cosmological models there is an ambiguity in the deduced radio luminosity; the Einstein–de Sitter model and the steady-state model are taken to illustrate the point.

The observed flux density per unit band-width from a source of luminosity $P(\propto \nu^{-x})$ situated at a distance r from the observer is $\dfrac{P}{r^2(1+z)^{1+x}}$, where z is the red-shift and P is the luminosity per steradian at the frequency of observation, not that of emission. The surface brightness may then be shown to be proportional to $\dfrac{P}{d^2(1+z)^{3+x}}$, where d is the linear dimension of the source. This result is similar to that given by Davidson[5] except that allowance has been made here for the spectrum of the source.

The formulæ quoted above apply both to the Einstein–de Sitter cosmological model and to the steady-state model, with the distinction that in the former r is equal to $\dfrac{2c}{H}[1-(1+z)^{-\frac{1}{2}}]$, and in the latter it is equal to cz/H, where H is the Hubble constant.

Observations at Jodrell Bank[6] and the California Institute of Technology[7] have indicated that for sources with a flux density at 159 Mc./s. of 10–20 $\times$ 10^{-26} W.m.$^{-2}$ (c./s.)$^{-1}$, the most frequently observed surface brightness, expressed as an equivalent temperature, is about 4 × 10^6 °K.

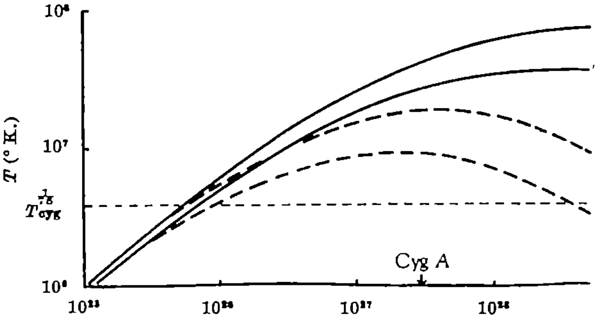

Fig. 1. Curves showing the relationship between the surface brightness temperature T and the source luminosity P for sources of given observed flux density. Two values of flux density are shown for: (*a*) the steady-state model (——); (*b*) the Einstein–de Sitter model (– – –). The upper line of each pair corresponds to a flux density of 20 × 10^{-26} W.m.$^{-2}$ (c./s.)$^{-1}$ and the lower line to 10 × 10^{-26} W.m.$^{-2}$ (c./s.)$^{-1}$. The curves are drawn for a value of the spectral index x = 0·8

The source Cygnus *A*, which has a flux density of 8,600 × 10^{-26} W.m.$^{-2}$ (c./s.)$^{-1}$ at 159 Mc./s., is known to consist of two components each of 50 × 30 sec. of arc. A mean value for the brightness temperature of this source for the type of observation made at Jodrell Bank is about 3 × 10^8 °K. Thus the most frequently measured brightness temperatures are about 1/75 of that of Cygnus *A*. If it is assumed that the other sources have a similar physical size to that of Cygnus *A* it is interesting to use the observed distribution of brightness temperatures to estimate an associated luminosity function.

For any particular range of the flux density S, Fig. 1 shows the variation of brightness temperature which would be observed for sources of different radio luminosity; separate curves are drawn for two different values of the flux density (S = 10 and 20 × 10^{-26} W.m.$^{-2}$ (c./s.)$^{-1}$). The luminosity is plotted in W.(c./s.)$^{-1}$ ster.$^{-1}$ at 159 Mc./s.; at this frequency the luminosity of Cygnus, ($P_{\rm cyg}$), is 3 × 10^{27} W.(c./s.)$^{-1}$ ster.$^{-1}$. The value for the source 3*C* 295 depends on the precise cosmological model adopted but probably lies in the range 3 × 10^{27} to 6 × 10^{27} W.(c./s.)$^{-1}$ ster.$^{-1}$.

It will be seen that at a typical value of surface brightness, $T = 1/75\ T_{\rm cyg}$, the Einstein–de Sitter model indicates two possible values of the source luminosity, and for an observed flux density of 10 × 10^{-26} W.m.$^{-2}$ (c./s.)$^{-1}$, these are 0·03 $P_{\rm cyg}$ and 11 $P_{\rm cyg}$.

If most of the sources so far observed have $P \simeq 0{\cdot}03\ P_{\rm cyg}$ (a value which would also agree with the predicted brightness temperatures according to a number of other cosmological models), then several hundred of the most intense sources would lie at distances less than that corresponding to $z = 0{\cdot}3$. If these sources are supposed to have an optical emission comparable with that of the Galaxy, they should be readily identifiable with visible galaxies.

The fact that most of them cannot be so identified[8,9] implies either: (*a*) that the optical emission is very much smaller than that of our own galaxy, in which case it is doubtful whether the corresponding physical dimension should be attributed to these sources in interpreting the measurement of angular diameter, or (*b*) that the sources are very much more distant and have powers comparable with or greater than that of the source in Cygnus. The latter interpretation would not require the hypothesis of a new class of radio source having a small optical emission.

PHYSICS

Measurement of the Mobility of Negative Ions in Saturated Hydrocarbon Liquids with High Electric Fields

A considerable volume of experimental data concerning the problems of high field conductivity and the electrical breakdown in liquid dielectrics is now in existence, and many theories have been proposed to explain these results. Nevertheless it is rather doubtful whether it will be possible to choose the right one without an understanding of the negative charge carriers and their high field mobility. With the exception of the measurements of Chong[1], there are no mobility data at high field strengths. On the contrary, a number of papers concerning the mobility of ions in low fields have been published[2-5]. The most systematic investigations concerning this problem were carried out by I. Adamczewski.

In the quantitative theories of high field behaviour it has been necessary to use mobility values measured in fields of a few kV./cm. Such an extrapolation must, however, be treated with precaution because the ionic nature of the negative charge carriers is still uncertain[6-7]. The necessity for high field mobility measurements has been pointed out quite clearly[8,9]. In order to help resolve some of these problems, I have measured the negative ion mobility in a number of *n*-paraffins for field-strengths up to 300 kV./cm.

The negative ion mobility as a function of field-strength has been measured by a method based on the metal–liquid photoemission phenomenon. Fig. 1 shows the schematic diagram of the apparatus. In this method the mobility is obtained from the linear temporal increase of current in the liquid ionization chamber circuit and not by measurement of the current pulse duration as has been done by LeBlanc[4]. With the arrangement used in his work the high field measurements were not possible.

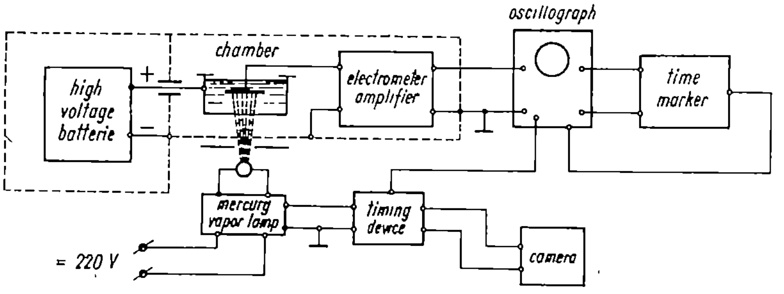

Fig. 1

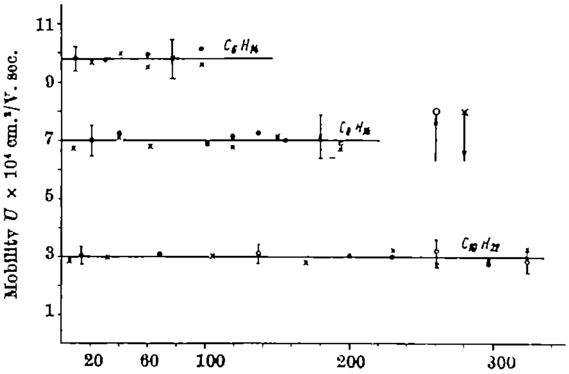

Fig. 2

For long ion transit times, the change in the sensitivity of photo-cathode as a result of 'fatigue' causes a distortion of the current pulse. In that case, better results are obtained by measuring the decay time of the current. These measurements can be carried out with the same apparatus except for a minor change in the working of the timing device.

The chamber used in the measurements differs in structure in several important details from other chambers described in the literature.

The cathode was illuminated through a transparent glass plate covered with a thin layer of stannum oxide. The transmission edge of the glass used lies significantly above the edge of the first absorption band of the hydrocarbons studied. In most measurements, the photo-cathode was a vacuum-deposited film of aluminium It was possible to arrange the electrodes exactly parallel by use of a ball joint with Wood's alloy. Adjustment of the spacing was carried out with the aid of an additional instrument with a micrometer screwed into the chamber. A glass vessel with a Schott *G*-4 filter, permanently connected to the chamber, was used for frequent rinsing of the chamber with the liquid sample.

Preparation of the liquid consisted of chemical processing, drying, fraction distillation and electrical cleaning. The final conductivity was about 10^{-19} Ω^{-1} cm.$^{-1}$.

The measurements of the current impulses were carried out with an electrometer amplifier of special construction connected to a direct current oscillograph. To reduce the time constant of the input circuit a system of negative feed-back was used.

In all measurements the source of ultra-violet light was a mercury vapour lamp with a *Q*400 bulb manufactured by Hanau.

The following liquids were selected for investigation: hexane, octane and decane. A series of liquid samples was studied with various electrode spacings, and for both increasing and decreasing electric stress. Changing the gap from 0·3 mm to 2 mm. gave the same result within the margin of error. In each liquid only one kind of negative ion was observed. The divergence among measurements resulting from changes in ambient temperature and from change of liquid sample remained, in most cases, within permissible limits.

The results of the measurements of the mobility of the ions as a function of the electric field strength are depicted graphically in Fig. 2. The range of the measurements was limited by the available high-voltage supply (10 kV.) and the rise-time of the light pulses (about 5 × 10^{-5} sec.). The results obtained indicate a lack of dependence on the field in the range studied. The possible experimental error introduced due to uncertainty in the electrode spacing was constant throughout each series of measurements, and considering only the dispersion of measured values the field independence is more clearly shown. Pyong-un Chong *et al.*[1], who measured the mobility in pure hexane and with the addition of 1 per cent ethyl alcohol for fields between 50 and 150 kV./cm., did not observe any dependence on the field either.

I thank Prof I. Adamczewski for his help and advice.

Mobility of Ions in Liquid Dielectrics

The first extensive investigations concerning the mechanism of the movement of ions in liquid dielectrics were undertaken by Adamczewski[1,2]. He investigated systematically a group of liquid-saturated hydrocarbons ranging from pentane to nonane, and formulated the empirical dependence between the viscosity of the liquid (η) and the mobility of ions (u), $u = A\eta^{-3/2}$. This dependence has been established by measurements at constant temperature.

In connexion with the investigations carried out by Gzowski and Terlecki[3], as well as LeBlanc[4], in which the existence of rapid negative ions has been determined, it was of interest to verify the above-mentioned formula for these ions, and to investigate its applicability at different liquid temperatures.

In this work measurements of the mobility of negative and positive ions produced by means of X-rays in *n*-hexane, *n*-heptane, *n*-octane, *n*-decane and mixtures of *n*-octane–*n*-hexane and *n*-decane–*n*-hexane in the range of temperatures from 8° to 50° C. have been made, using the 'layer method'[3]. All the liquids investigated had a residual conductivity $k \leqslant 10^{-13}\ \Omega^{-1}$ cm.$^{-1}$. The viscosity was measured using Hoeppler and Arrhenius viscosimeters.

Characteristic differences between negative and positive ions were observed. The mobility of negative ions in all these liquids was found to be greater than that of the positive ions. The transit time of the front edge of the negative ion layer was sharply defined, which indicated the existence of ions with small diffusion velocity. The diffuse velocity spectrum for positive ions showed that several kinds of ions were present. Because of the low resolving power of the apparatus, the mobility of only the most rapid positive ions has been determined.

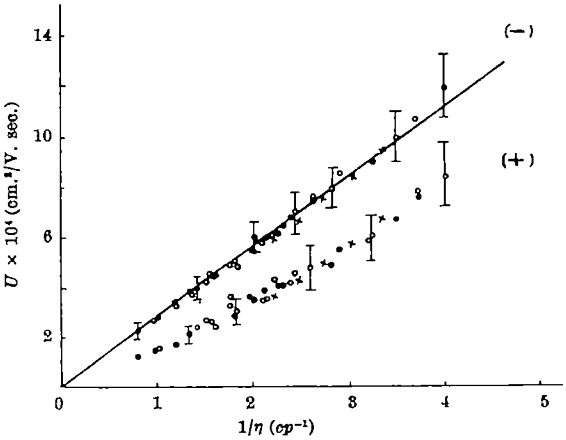

Fig. 1

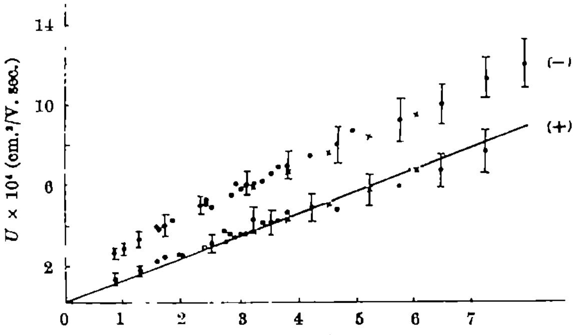

Fig. 2

Fig. 1 shows that the negative ion mobility may be expressed by the equation $u = B\eta^{-1}$, in agreement with Stokes's law, while Fig. 2 verifies that within the limits of the experimental error the positive ion mobility satisfies the equation $u = A\eta^{-3/2}$, where $A = 1 \cdot 2 \times 10^{-7}$ cm.^{2}/V. sec. poise$^{3/2}$. The crosses on both diagrams show results obtained for *n*-heptane. Detailed results and discussion will be published.

I thank Prof. I. Adamczewski for help in solving several problems connected with this work.

Birefringence induced by Acoustic Waves in Polystyrene Solutions

When an ultrasonic wave passes through certain liquids and solutions they exhibit double refraction and behave as uniaxial crystals with their optic axes lying along the direction of propagation of the acoustic beam. This effect, which may be called acoustic birefringence, was first observed by Lucas[1,2] and may be considered to be the result of a velocity gradient caused by the wave. Acoustic birefringence is related to flow birefringence in that both effects are caused by a similar mechanism. However, it appears that in liquids and solutions of small or flexible particles the distribution function defining the number of particles in a definite state of equilibrium during the passage of the acoustic wave is a function of frequency, whereas in flow the function is constant. Thus acoustic birefringence is oscillating and usually a root mean square value is measured. Also the oscillating birefringence is not in phase with the acoustic wave, the difference being dependent on the viscosity of the liquid and some molecular parameter. Studies of the effect are being made in this laboratory both on pure liquids and solutions.

Some results for polystyrene in toluene and chloroform are reported here. The apparatus has been briefly described elsewhere[3]. The polystyrene was a commercial sample of 'Lustrex' supplied by Monsanto Plastics, Ltd. The solvents were of analar grade and were not further purified. All measurements were made at 25° C. The intrinsic viscosity of the polystyrene in units of 10^2 cm.^{3} gm.$^{-1}$, found by measurements with a U-tube viscometer, was approximately unity. The kinematic viscosities varied from 6 to 45 cs. according to the concentration. In Fig. 1 a graph of r.m.s. birefringence, $\overline{\Delta n}$, against the square root of the acoustic intensity, $(\overline{\omega})^{\frac{1}{2}}$, is shown for polystyrene in toluene. From this a linear variation is seen. Fig. 2 shows the variation of $\overline{\Delta n}/(\overline{\omega})^{\frac{1}{2}}$ with frequency for three concentrations. Similar curves are found for polystyrene in chloroform.

A theory for the effect for solutions of flexible macro-molecules has been put forward by Peterlin[4], who, for dilute solutions, gives the r.m.s. birefringence as:

$$\overline{\Delta n} = n_0 \eta_0 c \, [M]_{\text{sp}} \left(\frac{\overline{\omega}}{\rho v^3}\right)^{\frac{1}{2}} \frac{\omega}{(1 + \omega^2 \tau^2)^{\frac{1}{2}}}$$

in which n_0, η_0 are the refractive index and viscosity of the solvent respectively, ρ is the density of the solution, v is the velocity and ω is the angular frequency of the acoustic wave. $[M]_{\text{sp}}$ is the specific Maxwell constant the value of which depends on the model assumed for the molecule[5]. Kuhn and Kuhn[6,7], Stuart and Peterlin[8] and Hermans[9] show that for polymers it is a function of the anisotropy of the polarizability of the molecule, the degree of polymerization, and the size and molecular weight of the monomer. τ is the relaxation time and provides a measure of the phase lag between the birefringence and the wave.

The observations shown in Figs. 1 and 2 are in general agreement with Peterlin's equation and, assuming the equation to be true, values of τ and $n_0\eta_0 c[M]_{\text{sp}}$ have been calculated. The results are summarized in Table 1. It appears that the relaxation time τ varies with concentration and tends to a limiting value as the concentration approaches zero, but it does not vary significantly with solvents having approximately the same viscosity. These values of τ are considerably smaller than the value calculated from viscosity data using the equation of Zimm[10] for dilute solutions, namely:

$$\tau = \frac{42 \, \eta_0 \, [\eta] \, M}{RT}$$

in which $[\eta]$ is the limiting viscosity number or intrinsic viscosity, M the molecular weight, R the gas constant and T the absolute temperature. This equation gives a value for τ of $3{\cdot}6 \times 10^{-6}$ sec. The difference between these values is possibly due to the fact that the viscosity value is an orientation relaxa-

Electron Distribution and Characteristic Temperature Variation at Low Temperatures in Magnesium and Ruthenium

A number of X-ray investigations on metals have indicated that over and above a uniform background of electron distribution, there exists electron density concentration at particular sites in the lattice. Brindley and Ridley[1] attributed the deviations of the measured X-ray scattering factors of ruthenium from a smooth curve to the existence of electron concentration at the mid-point of all the basal triangles formed by ruthenium atoms. Brill *et al.*[2,3] discussed for magnesium a similar concentration at only those triangle mid-points which are surrounded by five magnesium atoms. A similar effect, enhanced at 90° K., was found by Griffith and Harris[4] in lithium. Ageev *et al.*[5,6] interpreted their results on copper and nickel on the basis of bridge electrons corresponding to covalent bonds. On the other hand, other investigations on aluminium, silver, copper, nickel, chromium, etc., do not support the concentration of electron density. Theoretically, it is known that high-temperature factors used to eliminate the termination effect in Fourier series or errors in Fourier coefficients can lead to secondary maxima which could be interpreted as electron concentrations or bridge electrons.

If the concentration of electron density at lattice points not occupied by atoms is a real effect, then one can consider it as an extra scattering centre which modifies the scattering from atoms of the unit cell[7]. It effects the scattering factors of low-angle reflexions to show systematic deviations from a smooth curve. Deviations in the intensity of low-angle reflexions from theoretical values of about 5 per cent in magnesium and 12 per cent in ruthenium are expected on the basis of the above-mentioned observations[1-4]. To verify this effect, accurate measurements of scattering factors of magnesium and ruthenium at 296° K., 90° K. and 5° K. have been made by means of a scintillation counter. The scattering factor curves of both metals have been found to be smooth and do not show the expected systematic deviations. Therefore, no evidence has been found to support the hypothesis of the existence of electron density maxima in magnesium and ruthenium lattices at points other than those occupied by atoms.

The characteristic temperature has been calculated from the measured scattering factors. For magnesium, the values of characteristic temperature are found to be 315° K., 320° K. and 375° K. at temperatures of 296° K., 90° K. and 5° K., respectively. For ruthenium, at the same temperatures, values are found to be 350° K., 350° K. and 390° K. respectively. The value of 390° K. for ruthenium at 5° K. is rather uncertain in view of the smallness of the temperature factor. In any case, both hexagonal metals show an increase in the characteristic temperature at low temperature. A similar rise has been found from specific heat measurements on various hexagonal metals[8]. The latest specific heat measurements[9] of magnesium give characteristic temperatures of 326° K., 326° K., 389° K., 406° K., at temperatures of 296° K., 90° K., 10° K., 0° K. (extrapolated), respectively. The elastic constants data[10] of magnesium if extrapolated yield at 0° K. a value of 388° K. for the characteristic temperature. This rise in the characteristic temperature is not expected on the basis of Debye's simplified continuum theory but it can be explained by means of a detailed lattice theory.

CHEMISTRY

Magnetic Susceptibility Measurements of Iron (III) Form Ion Exchange Resin

It has been known for some time that the quantity of a tervalent metal sorbed on an ion exchange resin, in equilibrium with a solution of a salt of the same metal, varies, *inter alia*, with the *p*H value of the solution. In the case of indium (III)[1] and iron (III)[2] salt solutions it has been suggested that differences in uptake from the expected 0·333 gm. ion per equivalent of resin are caused by the presence in the solution of hydrolysis products.

According to Mulay and Selwood[3], the hydrolysed iron species $Fe_2(OH)_2^{4+}$, suggested by Hedstrom[4] and others, is diamagnetic and this fact has been used by Mulay and Selwood[3] to interpret the results obtained in investigations on the hydrolysis of iron (III).

For the present work, samples of cation exchange resin in the iron (III) form were prepared by equilibrating portions of the resin with solutions of ferric chloride having varying values of *p*H, and the magnetic moment of the iron sorbed on to the resin has been measured.

The iron form of the cation exchanger was prepared by passing, in large excess, solutions of ferric chloride (prepared from A.R. ferric chloride with the addition of A.R. hydrochloric acid where required) through a column of 'Zeo-Karb 225' resin in the hydrogen form. The resin was afterwards washed thoroughly with deionized water and, after air drying, was stored in a desiccator over calcium chloride.

Magnetic susceptibility measurements were made on a Gouy magnetic balance, allowance being made for the diamagnetism of the resin by running a blank magnetic weighing with the resin in the hydrogen form.

Table 1

Solutions					
[Fe]	[Cl]	pH	N_{Fe}	μ_r	μ_s
0·1	0·303	1·74	0·445	4·3	4·0
0·1	0·357	1·26	0·348	5·0	5·3
0·1	0·410	1·02	0·327	5·3	5·4
0·1	0·464	0·86	0·323	5·4	5·6
0·1	0·517	0·74	0·320	5·5	5·7
0·1	0·571	0·66	0·319	5·6	5·7

N_{Fe}, gm. ions of iron (III) per equivalent of resin. μ, magnetic moment in Bohr magnetons.

The results obtained are summarized in Table 1. The pH values (measured with a glass electrode and a calomel reference electrode on a commercial instrument) give some indication of the hydrogen ion concentration in the iron solutions examined. The amount of iron sorbed on the resin (N_{Fe} gm. ions per equivalent of resin) should be 0·333 for the saturation sorption of a tripositive ion. The increase in this value to 0·445 at pH 1·74 ([Cl$^-$] = 0·303) indicates sorption of ions having a positive charge of less than three associated with each iron atom. This can be accounted for by the presence of hydrolysed species such as $FeOH^{2+}$, $Fe(OH)_2^+$ and $Fe_2(OH)_2^{4+}$, possibly sorbed originally as chloro complexes. The decreases of the value of N_{Fe} to 0·319 at pH 0·66 ([Cl$^-$] = 0·571) would be accounted for by the sorption of unhydrolysed ferric ions (Fe^{3+}) together with an increasing number of hydrogen ions. The consideration that the decreasing sorption of iron is caused by changes in the quantities of hydrolysis products present is confirmed by the values of the magnetic moment for the iron present on the resin (μ_r). The increase in value of μ_r from 4·3 to 5·6 indicates that a diamagnetic ion is sorbed on to the resin from a solution low in free acid and that, as the acidity is increased, the iron becomes sorbed in the form of the spin free Fe^{3+} ion (magnetic moment of 5·9 Bohr magnetons). Included in Table 1 for comparison are values of the magnetic moment of iron in 0·04 M ferric perchlorate and 3 M sodium perchlorate solution (μ_s) calculated from the work of Mulay and Selwood[3]. Since the two sets of values for magnetic moment follow the same trend, it seems reasonable to draw the conclusion that hydrolysed species, as such, are present on the resin, and further, since the magnetic moments are similar in absolute value, that the various species are sorbed on to the resin in a ratio similar to that in which they exist in solution.

Stepwise Hydration of Clay-Organic Complexes

IT is well known that the hydration of many expanding clays occurs in several discrete steps during which up to four monolayers of water are successively admitted between the unit layers of the clay[1]. It is also well known that organic molecules or cations are often adsorbed between the unit layers in a stepwise fashion[2]. In this communication we report a novel phenomenon, the stepwise hydration of an organic complex. So far, we have encountered this phenomenon in sodium Wyoming bentonite–α-picoline–water systems, in which as many as five discrete hydrates could be distinguished, and in sodium Wyoming bentonite–pyridine–water systems, in which two discrete hydrates were observed.

When a flake of dry sodium Wyoming bentonite is immersed in dry α-picoline, an adsorption complex with a c spacing of 15·9 Å. is obtained. On equilibration of the flakes with solutions of water in α-picoline of increasing concentration, the successive formation of hydration complexes with the following c spacings occurs:

Percentage of water in α-picoline	0	2	5	10	15	20	25	30	40	50
c spacing (Å.)	(15·9)	21·9	21·9	*d*	25·7	27·9	27·0	*d*	31·8	33·8

The X-ray patterns showed six or more integral orders, except at the water concentrations of 10 and 30 per cent, at which broadening of the lines and disorder of the patterns indicated that the next hydrate was not yet fully developed. Above a water content of 50 per cent, the flakes disintegrated spontaneously, and the X-ray patterns became diffuse.

When a flake of dry sodium Wyoming bentonite is immersed in thoroughly dried pyridine, a complex with a c spacing of 19·4 Å. is obtained. When the clay flakes are equilibrated with solutions of water in pyridine of increasing concentrations, the c spacing increases as follows:

Percentage of water in pyridine	0	2	5	10	15	20	25	30	35	40	45	50	55
c spacing (Å.)	(19·4)	*d*	*d*	23·3	23·3	23·3	*d*	*d*	*d*	29·3	29·3	29·3	29·3

At water contents of more than 55 per cent, the flakes disintegrate. The 23·3-Å. complex is also formed when the dry complex with the 19·4-Å. spacing is exposed to the laboratory atmosphere (relative humidity of about 50 per cent). (The formation of the 19·4-Å. complex, which has not been reported before, requires intensive drying of the clay and of the pyridine liquid, preferably with Linde 4A molecular sieve material. Greene-Kelly[3] observed the 23·3-Å. complex and recognized that the formation of this complex required the presence of traces of water in the system.)

Without presenting a detailed argumentation in this brief communication, we propose the following interpretation of the hydration phenomena.

In the completely anhydrous condition, the c spacing of the clay immersed in pyridine is 19·4 Å. Another complex observed in the earlier stages of adsorption from a pyridine solution in a hydrocarbon fluid has a c spacing of 14·8 Å. In the latter complex, the pyridine molecules are in an upright position, with the ring nitrogen and associated sodium exchange cations in a midway position between the unit layers (cf. Greene-Kelly[4]). In the 19·4-Å. complex, two layers of upright pyridine molecules are probably superimposed, possibly in a slightly tilted or partially overlapping position. The ring nitrogen and the sodium ions are probably again located in the plane midway between the unit layers. According to density determinations on the clay in pyridine, the pyridine molecules between the unit layers are in a closely packed condition.

On hydration, water molecules are likely to associate with the midway cations and ring nitrogen groups, causing a parting of the two superimposed, closely packed pyridine layers. The hydration is accompanied by an increase of the *c* spacing of 3·9 Å., which is more than the cross-section of a water molecule. Possibly, a re-orientation of the previously tilted or overlapping pyridine rings occurs, which is allowed by a decrease of the attractive force between the negative unit layers and the midway layer of cations with increasing distance. The formation of the second discrete hydration complex with a 6·0-Å. higher basal spacing can be explained by the entrance of two monolayers of water in the first hydration complex.

In the α-picoline system, when no water is present, only a complex with one layer of upright ring molecules is obtained with a *c* spacing of 15·9 Å. According to density determinations in liquid α-picoline, the interlayer molecules are less closely packed than in the liquid state, possibly because of the unfavourable packing geometry of these molecules in a monolayer. Probably for the same reasons, a two-layer complex analogous to the 19·4-Å. pyridine complex does not occur. Only in the presence of water are two-layer complexes formed, the 21·9-Å. complex being comparable with the first hydration 23·3-Å. complex of pyridine. The fact that the *c* spacing of the α-picoline hydration complex is smaller than the *c* spacing of the pyridine hydration complex in spite of the larger cross-section of the α-picoline molecules is probably a consequence of the less dense packing of the latter, which permits the water molecules to occupy midway positions without parting the two α-picoline layers.

In the formation of the next series of discrete hydrates, the irregularity of the successive steps in basal spacing would indicate that simultaneous re-orientations of the organic molecules occur.

These interpretations are still somewhat speculative, since we have no definite data on the composition of the various complexes. Although data on adsorption from solution are difficult to interpret unless certain assumptions on the relative adsorption of the two components are made, we shall attempt to obtain further information on the composition of the complexes from such data.

The X-ray diffraction patterns were obtained by Mr. W. K. Lumb, E. and P. Research Division, Shell Development Company.

Manufacture of Alkali-free Corundum of Tabular Crystal Form

THERE are several modifications of aluminium oxide, the most important of which are α- and γ-forms. The latter cannot be considered as aluminium oxide proper, since it contains substantial quantities of alkali oxide. α-Aluminium oxide, corundum, constitutes the basic material of several ceramic products or plays an important part in the formation of some of these products[1].

γ-Aluminium oxide is formed at low temperatures by the dehydration of aluminium hydroxide. This modification is converted at temperatures exceeding 1,000° C. monotropically into the α modification. α-Corundum crystallizes in the ditrigonal-scalenohedral crystal class, forming squat or column-like elongated crystals. Until now, crystals of the tabular form could be obtained only when the basic material contained small quantities (0·2–1·5 per cent) of alkali oxide.

The bending strength and the compactness of products prepared from corundum are of importance in industry. Tabular corundum is used also as a colour pigment. α-Corundum in the tabular crystal form has several advantages from the technical point of view. Higher compactness, increased bending strength and higher sintering-rate may justify its use for the production of sintered corundum, for apart from being of tabular form it is also free of alkali. It is characteristic of the tabular form that the longitudinal and lateral dimensions of the crystal are are least 4–5 times its thickness. If a product of high purity is required, the addition of alkali oxide for the promotion of the development of the tabular form is to be avoided.

In a new process developed, tabular α-corundum is obtained as an end-product when aluminium fluoride (AlF_3) is hydrolysed with steam at a temperature above 800° C. Thermal treatment of aluminium fluoride is carried out expediently under fluid conditions. It is rendered fluid by a mixture of steam and air. Below 800° C. no pure corundum is obtained, because hydrolysis proceeds only when the equilibrium fluorine content is attained. Depending on the temperature, the fluorine content of the product thus obtained varies between 4·8 and 4·0 per cent. The end-product contains substantial quantities of aluminium oxy-fluoride besides α-corundum[2].

Hydrogen fluoride is also formed in the reaction, and this can be used for the manufacture of aluminium fluoride. The hydrolysis of aluminium fluoride begins at 300° C. Below 300° C. aluminium fluoride is formed from aluminium hydroxide or aluminium hydrate, when treated with hydrogen fluoride. This heterogeneous reaction is carried out most advantageously in the fluid state.

Fluidization is justified by an increase in reaction-rate in the fluid bed, as compared to the fixed bed. If the rate of a process is determined by external diffusion, this rate is substantially increased by the continual movement of the particles. The capacity of the fluidizing oven is further increased because the reaction zone occupies its greater part.

The absence in most cases of moving parts in the equipment constitutes another advantage of the process, and facilitates the handling of the equipment. Its working is easy, and little manpower is required for its operation.

Both the hydrolysis and the manufacture of aluminium fluoride became continuous operations by applying the fluidized process. Material handling was simplified by connecting pneumatic conveyors to the reactors. Owing to good heat transmission, uniform temperature is established in the fluid system.

Advantages from the industrial point of view are: (1) relatively low investment costs; (2) high capacity; (3) continuous operation; (4) uniform heat distribution in the bed; (5) high heat transmission-rate; (6) simple apparatus; (7) low labour requirement.

Hydrogen fluoride liberated during the production of corundum may be used for the manufacture of aluminium fluoride. Two vertical fluidizing ovens, which may be placed one above the other, are needed for the re-circulation of hydrogen fluoride. In the lower oven aluminium fluoride is fluidized at a temperature of above 800° C. in the presence of steam. α-Aluminium oxide of tabular form and hydrogen fluoride leave the unit. The latter may be introduced directly into the other oven, in which aluminium hydroxide or aluminium hydrate is fluidized at a temperature of 250–280° C. Aluminium fluoride, produced in this unit, may be used in the first unit for the production of tabular α-aluminium oxide.

Mechanism of Ethylene Hydrogenation

ELEY[1], in his article on ethylene hydrogenation, points out several treatments for developing the half-hydrogenated state, which then is converted to ethane. Basically these are: (1) the Polanyi and Greenhalgh[2] treatment:

$$^{*}CH_2—CH_2{}^{*} + H^{*} \underset{K_{-1}}{\overset{K_1}{\rightleftarrows}} {}^{*}CH_2—CH_3 + H^{*} \xrightarrow{K_2} CH_3CH_3$$

which requires an essentially equivalent and ideal adsorption of hydrogen and ethylene on a uniform surface, and (2) the Twigg[3] mechanism, which postulates that the reaction of hydrogen on ethylene-metal can occur only by reaction of the hydrogen with chemisorbed ethylene:

$$^{*}CH_2—CH_2{}^{*} + H_2 \underset{K_{-1}}{\overset{K_1}{\rightleftarrows}} {}^{*}\,CH_2CH_3 + H^{*} \xrightarrow{K_2} CH_3CH_3$$

In the case of the nickel catalyst, which has been the most investigated metal, many of the results seem to favour, although they do not completely establish, the Twigg mechanism for the half-hydrogenated state.

I have conducted experiments with hydrogen and hydrogen–ethylene mixtures over electrodes impregnated with platinum in a fuel cell, and the results lend support to the Twigg mechanism. Equivalent electrodes, composed of 3 per cent platinum on carbon disks, were used as cathode and anode in a cell containing 20 per cent potassium hydroxide as electrolyte. This cell at 35° C. developed 1·00 V. open circuit, and yielded a current of 25 amp./ft.^{2} at 0·3 V. when hydrogen was fed to the anode and air to the cathode. However, when a mixture of gases containing 29·1 mole per cent hydrogen, 68·3 per cent ethylene, and 2·2 per cent ethane was used in place of hydrogen, 0·19 V. open circuit and less than 0·3 amp./ft.^{2} of current under load were obtained. This indicates that the participation of the hydrogen in the fuel cell reaction, that is, the oxidation to water, was virtually eliminated. However, the effluent from the fuel chamber contained 1·0 per cent hydrogen, 57·8 per cent ethylene and 40·8 per cent ethane, and indicated that the hydrogenation of ethylene was occurring smoothly. At 85° the hydrogen concentration fell to 0·1 per cent. Since the rate of the hydrogen–oxygen cell reaction is essentially zero at open circuit conditions, the potential should be maintained if anything approximating an equivalent amount of hydrogen is adsorbed even if the hydrogenation reaction is considerably faster than the oxidation. The sharp fall in open circuit potential and current density indicates that no hydrogen is adsorbed, hence the reaction of hydrogen on ethylene–platinum proceeds by the attack of the molecular hydrogen on the activated ethylene.

During the hydrogenation of isobutene, on the other hand, the hydrogen and olefine occupy approximately equal fractions of the surface[4]. Thus, while ethylene molecules can pack in such a way as to fill the surface and exclude chemisorbed hydrogen, the bulky nature of the methyl ethylenes necessarily leads to bare sites which can chemisorb hydrogen. In agreement with this I found that isobutene–hydrogen mixtures under the same cell conditions gave 0·57 V. open circuit and 2·8 amp./ft.^{2} under load.

Correlation of Biological Activity of Phenoxyacetic Acids with Hammett Substituent Constants and Partition Coefficients

IN the 'two-point attachment' theory[1] on the mechanism of action for growth regulators of the auxin type we have assumed as a working hypothesis that the reaction between auxin and substrate is more chemical than physical in nature and that covalent-bond formation is a possibility. The need for an aromatic ring with at least one unsubstituted position for auxin activity[2] confirms our original belief that an *ortho* position in the phenoxyacetic acids is most suitable stereoelectronically to serve as one of the two points which attach the molecule to the plant substrate. The carboxyl serves as the second point, permitting the auxin to form a ring when joined to a plant protein. This reaction mechanism is supported by the work of Bonner *et al.*[3,4].

If a specific position on the aromatic ring is involved, and not the ring as a whole, then an examination of the effect of substituents should indicate what the ideal electronic character of this point should be. Early qualitative work[5] indicated that groups which lowered the electron density at the *ortho* positions gave increased biological activity in the phenoxyacetic acids. Calculations of pi-electron delocalizability have been of qualitative value in rationalizing auxin activity in the benzoic acids[6,7]. However, the use of Hammett sigma functions to establish a quantitative relationship between electron density at the *ortho* position and auxin activity have not been successful, although electron-attracting groups are more effective in promoting auxin activity than are electron-releasing groups.

$$\text{Solution} \xrightarrow{k_1} \text{site of action} \xrightarrow{k_2} \begin{array}{c}\text{one point}\\ \text{attachment}\end{array} \xrightarrow{k_3}$$

$$\begin{array}{c}\text{two point}\\ \text{attachment}\end{array} \xrightarrow{k_4 \rightarrow k_n} \text{growth}$$

The formulation of a precise relationship requires that several major steps in the auxin effect which may be rate controlling be considered. Growth here is measured as the elongation of 3 mm. segments of *Avena* coleoptiles when grown under conditions yielding a linear growth-rate[3]. This sequence indicates that the first possible rate-determining event in the auxin effect may be the penetration to the site of action where, after proper orientation, two point attachment occurs initiating a complex series of events ($4 \rightarrow n$) which are manifested in growth. Considering the large number of molecules with greatly different structures which effectively promote growth, it seems likely that the auxins act to initiate the growth process, but that they are not involved in steps $4 \rightarrow n$. That k_3 can control rate is shown by the inactivity of the 2,4,6-trisubstituted phenoxyacetic acids. That k_2 may be rate controlling is shown by the inactivity of many α,α-disubstituted phenoxyacetic acids.

It occurred to us that lack of success in applying the Hammett linear free-energy relationship to rationalize the effect of substituents on auxins such as phenoxyacetic acids was due to the failure to take into account k_1. The concentration of auxin at the site of action will depend on the rate of penetration of the various substances through the aqueous and organic portions of the plant cell. This rate of penetration might be approximately proportional to the partition coefficient of the auxin between water and a relatively non-polar organic solvent. That is, there should be an ideal hydrophilic–lipophilic character for a given type of auxin so that it would not tend to remain either in the aqueous phases or the organic phases of the cell, but move at an optimum rate to the site of action. To evaluate this hypothesis we have determined the partition coefficients (P) for a series of phenoxyacetic acids between 1-octanol and water at 30 ± 1°. The general procedure was to partition 20 mgm. of acid between 20 ml. of octanol and 200 ml. of water. For some of the auxins with high P values 25 ml. of octanol and 400 ml. of water were more suitable. For 3-OH and 3-COOH 150 ml. of octanol and 50 ml. of water were used. The octanol was saturated with water free of carbon dioxide and the water was saturated with octanol. For partitioning, the mixture was shaken vigorously for 1½ hr. after which the water layer was withdrawn and centrifuged at 2,500 r.p.m. for 1½ hr. Centrifuging was very important for complete separation of the octanol even in those samples in which no visible emulsification occurred. The amount of auxin in the water layer was determined coulometrically[8]. All operations were carried out under nitrogen to avoid contamination by carbon dioxide. For a number of acids a series of partitions was made over a range of concentrations. This permitted the calculation of the degree of association of the acids in the octanol layer. For acids as diverse as phenoxyacetic acid and 3-nitrophenoxyacetic only about 2·0 per cent association occurred at the concentrations used (of the order of 1×10^{-3} M). The association in the organic layer was ignored, and the expression used for the partition was $P = \dfrac{C_{\text{octanol}}}{C_{\text{H}_2\text{O}}(1-\alpha)}$. The degree of dissociation in the water (α) was calculated from the ionization constants, a number of which have been determined[9]. Those for which experimental values were lacking were calculated by the Hammett relationship[10]. It has been assumed that the rate of penetration of the auxin to the site of action will be a parabolic function of the partition coefficient. For simplicity in calculations we have used $\pi = \log P - \log P_H$, where P_x is the partition coefficient of the substituted phenoxyacetic acid and P_H that of phenoxyacetic acid. Modifying the Hammett equation to compensate for the relative rates of penetration we obtain $\log 1/C = k\pi + k'\pi^2 + \rho\sigma + k''$. C is the concentration in moles/litre of auxin which induces 10 per cent growth in the *Avena* cylinder test. It was observed for low concentrations of auxin (that causing less than 30 per cent elongation of the sections) that the rate of growth was proportional to log C. The evaluation of the constants k, k', k'' and ρ for the best fit to the experimental data was done with a Clary *DE*-60 computer. Sigma was chosen with respect to the *ortho* position, that is, for a substituent in the 4 position σ_m was used and for one at the 3 position σ_p was used. Compounds with large groups in the 4 position were not included since we have found Åberg's observation[11], that large substituents in the 4 position cause inactivity, to hold for a wide variety of groups.

The results given in Table 1, obtained from the expression $\log 1/C = 4{\cdot}08\pi - 2{\cdot}14\pi^2 + 2{\cdot}78\sigma + 3{\cdot}36$, show that an increase in activity of the substituted phenoxyacetic acid occurs with increase in sigma or as the partition coefficient is increased, sigma being held constant. Activity falls to zero with high values of P (compare 3-CH_3, 3-C_2H_5, 3-n-C_3H_7 and 3-n-C_4H_9, where the values for sigma are essentially constant). The most convincing evidence, other than that previously reported[1,2], for using the value of sigma at the *ortho* position is that a considerably better fit of the data with the above type of equation is obtained. Particularly striking is the comparative activities of the 3- and 4-F and 3- and 4-Cl acids. In each pair of isomers the value for π is almost the same for the 3 and 4 positions. The way in which the two halogens affect the electron density at the *ortho* positions by resonance is, however, quite different especially in the example of the fluorine. The dramatic difference in activity between the 3- and 4-fluorophenoxyacetic acids seems best explained in terms of the different electron densities at the *ortho* positions. Differences in steric and *H*/*L* factors would be the smallest possible. The result with chlorine is the same although less pronounced. In the case of the 4-F derivative the activity found is actually much greater than that predicted. At present it is not possible to offer a rationalization

Table 1

Substituent	σ	P	π	log 1/C (calc.)	log 1/C (obs.)
3-CF_3	0·55	330	1·09	6·8	6·5
4-Cl	0·37	168	0·80	6·3	6·4
3-I	0·28	325	1·08	6·1	6·3
4-F	0·34	43	0·20	5·0	6·3
3-Br	0·23	254	0·97	5·9	6·0
3-SF_5	0·68	1,190	1·64	6·2	6·0
3-Cl	0·23	178	0·82	5·9	5·7
3-NO_2	0·78	29	0·04	5·7	5·3
3-SCH_3	−0·05	105	0·59	4·9	5·3
3-C_6H_5	−0·15	200	0·87	4·9	5·3
3-*n*-C_3H_7	−0·15	890	1·52	4·2	4·7
3-OCH_3	−0·27	36	0·13	3·1	4·7
3-CN	0·63	16	−0·23	4·1	4·5
3-CH_3	−0·17	75	0·44	4·3	4·3
3-CH_3CO	0·52	22	−0·08	4·5	4·0
3-F	0·06	41	0·18	4·2	3·5
H	0·00	27	0·00	3·4	3·5
3-OH	−0·36	5	−0·73	−1·8	3·7
3-COOH	0·27	21	−0·13	3·5	3·0
3-*n*-C_4H_9	−0·15	3,100	2·08	2·4	0·0

for this or for 3-CH_3O and 3-OH, which are also poorly predicted. It is not surprising that the activity predicted at log $1/C = 2·4$ for 3-*n*-C_4H_9 is not realized. Most growth regulators are inactive at concentrations as high as 10^{-3} *M*.

Discussions with other investigators of the correlation of biological activity and chemical structure indicate that in both plant and animal systems where steric and metabolic factors can be ruled out, the use of Hammett functions and partition coefficients will be of significance in rationalizing structure and activity.

We are indebted to Prof. Alvin Beilby for advice in the coulometric determinations, to Mr. C. F. Geiger for the synthesis of several of the acids, to Prof. Donald McIntyre for instruction in curve fitting with the Clary computer, and to Prof. R. Nelson Smith for many helpful suggestions in the determination of the partition coefficients. We also thank Dr. W. A. Sheppard of the DuPont Co. for a sample of 3-pentafluorosulphurphenol and for the sigma values for the SF_5 group.

This work was supported in part under research grant 7492 from the National Institutes of Health.

RADIOCHEMISTRY

Beta-Scintillation Counting of Radioactive Tracers Insoluble in Toluene

Liquid scintillation in certain organic solvents is acknowledged in principle to be among the most sensitive methods of estimating radioactivity from weak β-emitters such as carbon-14, especially in low concentration. In the presence of water, however, the normally high efficiency of β-scintillation counting in toluene is seriously impaired[1]. Blending of aqueous samples with large volumes of liquid scintillator in toluene by addition of organic solvents[2] results in appreciable lowering of counting efficiency and in a tendency to precipitate the solute. Samples counted in suspension[3] require extrapolation to zero sedimentation. Packing of aqueous solutions with scintillator beads[4] is expensive, and accurate counting with anthracene suspensions[5] is time-consuming. Incorporation of aqueous samples into gels[6] is not always practicable for counting at low temperatures.

In this laboratory we have felt the need of a method for counting aqueous samples containing very small amounts of carbon-14. A new approach found useful consists of applying the aqueous sample to strips of lens tissue, which are then dried, cut into small pieces and loaded into the counting vessel. Sufficient liquid scintillator in toluene is added to immerse the whole mass of the tissue. The solvent pervades the tissue and renders it translucent. Among advantages of this procedure are: (1) simplicity, and economy in time and materials; (2) high sensitivity; (3) linear variation of response with activity of a standard; (4) small sacrifice of counting efficiency; (5) ability to recover the toluene-insoluble sample.

Up to 0·1 ml. of aqueous solution is uniformly pipetted on to 2 cm. × 12·5 cm. strips of lens tissue supported vertically. After drying in a current of warm air, further 0·1-ml volumes of sample may be applied. Each strip is cut into squares of about 0·2 cm., and these are lightly packed into ampoules. I have found 5 ml. dispensary ampoules useful containers (see also Hubscher *et al.*[7]). Scintillation fluid (2 ml. of 2 gm. *p*-diphenyloxazole per litre toluene) is run into each ampoule without entrapping air bubbles. The ampoules are pre-cooled at −20° C. in the dark for 30 min. (Sealing of the ampoules is unnecessary if they are counted within 6 hr.). For coloured samples, or samples containing much dissolved solid, glucose-1-^{14}C is used as internal standard to correct for quenching. For counting, one of the standard cuvettes for the *EKCO N*612 scintillation head is first placed in position above the shutter and the phototube with which optical contact is made in silicone fluid *MS* 200/2. Each ampoule containing the scintillator is then placed in turn in the centre of the cuvette in a pool of ethanol (3 ml.) which serves both as contact fluid and demisting agent.

The validity of this technique was assessed as follows: the voltage setting on the scaler was chosen so that the function $\frac{R_s^2}{R_b}$ was a maximum[8], where R_s and R_b were the observed counting-rates of sample and background respectively. Using our instrument the practical upper limit of this function at the 1-mμc. level was about 1,000. The counting efficiency $\left(\frac{\text{counts per second}}{\text{disintegrations per second}} \times 100\right)$ was then 39 per cent. The presence of lens tissue lowered this efficiency by no more than 3·4 per cent. To gauge reproducibility, the coefficient of variation among six replicate determinations was calculated for different low levels of activity, monitored in duplicate for 4,000 counts or 1,000 seconds, whichever was shorter. Counting samples for longer periods was rarely practicable where large numbers of samples were to be monitored. Activities were expressed as mμc, referred to a glucose-1-^{14}C standard based in turn on a toluene-reference standard, making due allowance for the presence of lens tissue.

The coefficient of variation of replicate counts of a single sample, expressed as a percentage of mean counts per sec., is found to be 5·9 for 0·01 mμc., 3·3 for 0·1 mμc. and 2·2 for 1 mμc. samples. The coefficient of variation of counts on replicate aliquots of the same sample are less than 2 per cent higher, showing that only a very small proportion of the total error is attributable to sample preparation.

I have found this technique particularly useful for the radioassay of biological fluids such as urine. It lends itself readily to the analysis of large numbers of samples in a variety of solvents. The samples can be recovered from the tissue by washing with toluene to remove scintillator, drying and extracting with water.

I thank Dr. P. Armitage of the Statistical Research Unit, London School of Hygiene and Tropical Medicine, for statistical advice. The work was undertaken as part of a programme financed by the British Empire Cancer Campaign.

BIOPHYSICS

Scattering Cross-Section of Carbon at Small Angle

In a previous communication[1] it was shown that, in the angular range $\alpha < 10^{-2}$ radian, the values of the scattering cross-section of carbon for 50-kV. electrons as calculated from electron scattering formulæ[2] do not satisfactorily agree with experimental results. The above theoretical calculation was based on Wentzel atomic radius as given by $R = a_{\mathrm{H}}/Z^{\frac{1}{3}} = 0{\cdot}29$ Å. However, if, according to Lenz[2], R is expressed as $((\mathrm{H})/6Z)^{\frac{1}{2}}$ with $(\mathrm{H}) = 16{\cdot}58\ a_{\mathrm{H}}^{2}$ on Hartree atom model and $(\mathrm{H}) = 7{\cdot}60\ a_{\mathrm{H}}^{2}$ from diamagnetic susceptibility value, the magnitude of the respective atomic radii becomes 0·36 Å. and 0·24 Å.

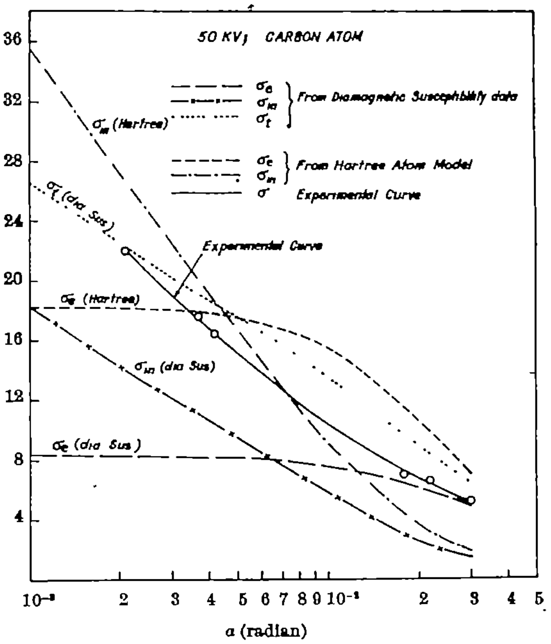

Fig. 1. Theoretical and experimental values of scattering cross-section of carbon for 50 kV. electrons at small angle; experimental points from De (ref. 1), theoretical curves from Lenz (ref. 2)

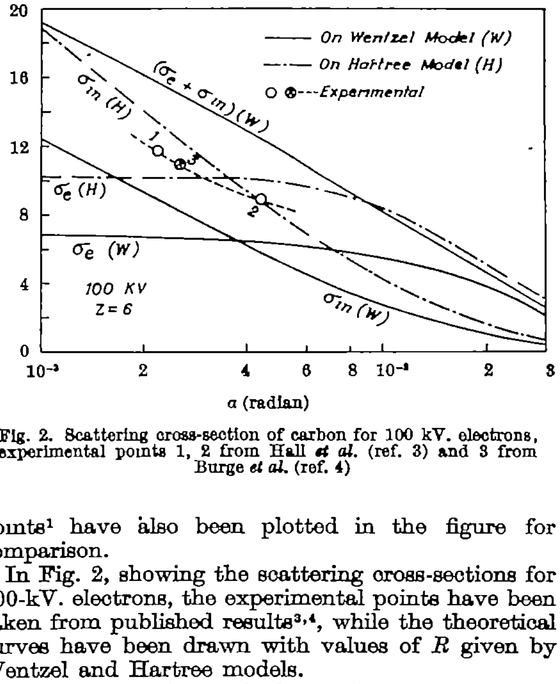

Fig. 2. Scattering cross-section of carbon for 100 kV. electrons, experimental points 1, 2 from Hall *et al.* (ref. 3) and 3 from Burge *et al.* (ref. 4)

With these two values of R, the corresponding theoretical scattering cross-section curves for 50 kV. electrons are represented in Fig. 1, where σ_e and σ_{in} signify the elastic and inelastic cross-sections respectively and $\sigma_t = \sigma_e + \sigma_{in}$; my earlier experimental points[1] have also been plotted in the figure for comparison.

In Fig. 2, showing the scattering cross-sections for 100-kV. electrons, the experimental points have been taken from published results[3,4], while the theoretical curves have been drawn with values of R given by Wentzel and Hartree models.

On a comparison of the various experimental results with theoretical values it can be concluded that with none of the values of R as considered above, one can get theoretical values of scattering cross-section agreeing satisfactorily with experimental results. Obviously, a reconsideration of the scattering formula or of the appropriate atomic radius seems to be necessary for the small angle region of scattering, which angular range is of particular importance in electron microscopic work.

BIOCHEMISTRY

Radiosensitivity of Hydrogen Bonds in Deoxyribonucleic Acid

ALEXANDER *et al.*[1] have suggested that the 'secondary' structure of deoxyribonucleic acid (DNA) is disorganized after irradiation by breaking the hydrogen bonds which link the two molecules together into the twin helix. "In regions of the DNA molecule where this occurs, the double molecule is opened up and becomes more flexible." The molecule can coil up then into a smaller volume in solution and the viscosity of this solution will decrease. A further decrease in the viscosity is observed when the molecule is degraded due to breaks in the polynucleotide chain. As the loss of the viscosity is a result of different radiation effects, it is of interest to study the effect of the irradiation on the hydrogen bonds with other methods. The work of Sarkar and Dounce[2] provides a basis for such studies. According to these authors the formaldehyde reaction of Fraenkel-Conrat[3] can be observed only when an appreciable disruption of the interstrand hydrogen bonds occurs. This formaldehyde reaction may be more sensitive than viscosity measurements for detecting a low degree of denaturation of DNA. While Sarkar and Dounce[2] studied the denaturation after heating, I compared their results with the denaturation by X-ray irradiation.

Purified DNA (Worthington) is dissolved in 0·01 *M* sodium chloride (0·03 mgm./ml.), adjusted to *p*H 5·6–6·0 and irradiated with X-rays (Siemens-Dermopan X-ray machine; 50 kV., 25 m.amp, 140 kr./min.). Immediately after irradiation 0·1 ml. of 40 per cent formaldehyde, previously adjusted to *p*H 7·0, was added to 3·0 ml. of the DNA solution and the mixture was allowed to stand at 37° C for 1 hr. The absorption spectrum of the mixture was then determined (in terms of extinction) between 210 and 300 mμ with the recording spectrometer 'Spectronic 505' of Bausch and Lomb. As 'controls' unirradiated DNA-solutions before and after heating (10 min. at 90°) were used. A typical experiment is shown in Fig. 1.

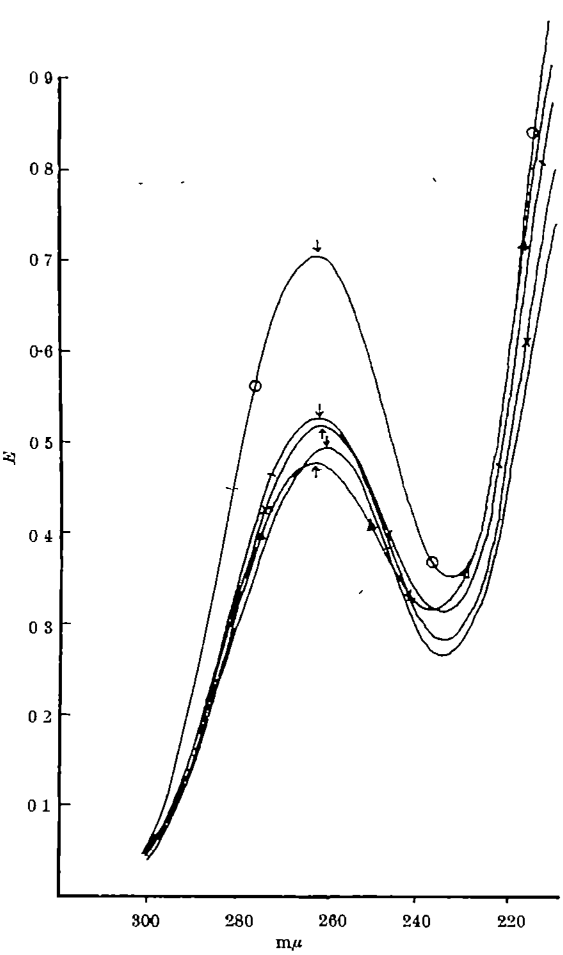

Fig. 1. DNA (Worthington), 0·03 mgm./ml. in 0·01 *M* sodium chloride. Absorption spectrum between 200 and 300 mμ after adding 0·1 ml. formaldehyde to 3·0 ml DNA solution. ———, DNA, unirradiated, —×—×—, DNA, immediately after 70 kr., —I—I—, DNA, immediately after 140 kr ; –Δ–Δ–, DNA, immediately after 210 kr.; —○—○—, DNA, 10 min. heating at 90° C. The arrows indicate the position of the maximum

The results of Sarkar and Dounce[2] were confirmed; after heating there was an increase of the extinction and a spectral shift in the position of the maximum by 2–3 mμ. A shift of this maximum is observed also after irradiation with doses of 70–210 kr. Higher doses do not produce more changes in the position of the maximum. However, the increase of the extinction after irradiation is much lower than after heating and is not dependent on the dose of X-rays used. Without formaldehyde there is an increase of the extinction after 70 and 140 kr.; higher doses render a decrease. The irradiation effect on the formaldehyde reaction and the decrease of the viscosity of the DNA-solution were compared. The shift in the position of the maximum toward unirradiated DNA has been measured after irradiation with 70, 140, 210 and 420 kr. In Table 1 the average values of the shift (6 experiments each) are compared with the intrinsic viscosity. The determination of the viscosity is described in an earlier publication[4].

Corresponding with the results of Sarkar and Dounce[2], there is no decrease in the viscosity after heating, whereas a considerable shift of the maximum can be observed. As in the heating experiments of Sarkar and Dounce, it was also found in the irradiation experiments that the formaldehyde reaction is a more sensitive method than the measurement of the viscosity. Whereas after 210 kr. the formaldehyde reaction is nearly complete, the viscosity of the solution decreases only to values of 66 per cent of the control. This loss of viscosity is in fairly good agreement with the results of Lett and Alexander[5].

Table 1. FORMALDEHYDE REACTION AND VISCOSITY AFTER IRRADIATION IN DNA SOLUTIONS

Dose (kr.)	Shift of the position of the maximum at 260 mμ (in mμ)	Intrinsic viscosity [η]
0	0	23·4
70	1·0 ± 0·15	20·4
140	2·0 ± 0·10	18·0
210	2·95 ± 0·20	15·5
420	3·20 ± 0·25	12·8
10 min 90° C.	2·50 ± 0·30	24·2

These experiments suggest that the hydrogen bonds in the DNA molecule are broken by low doses of X-rays. The molecule becomes more flexible and loses only little of its viscosity. Breaks of the nucleotide chain leading to a further decrease of the viscosity seem to occur mostly after higher doses. DNA, extracted from the thymus 3–6 hr. after 1,000-r. whole-body irradiation, shows a considerable change in viscosity decreasing to 50 per cent of the control[4]. This degraded DNA, prepared from the thymus of irradiated animals according to Kirby[6], does not, however, show any formaldehyde reaction at all. There is no difference in the absorption spectrum before and after incubation with formaldehyde, whereas after heating, a shift of the maximum and an increase of the extinction can be observed. Here, after irradiation *in vivo*, the decrease in viscosity is a much more sensitive method than the formaldehyde reaction. This supports the idea[4] that ionizing radiation destroys the DNA *in vivo* by quite different mechanisms than *in vitro*.

Accelerated Collagen Formation and Histamine

IT has recently been demonstrated that reparatively growing tissues in skin wounds in the rat produce histamine at a high rate as a result of increased activity of histidine decarboxylase[1]. Further, the rate of repair, as measured by the tensile strength of the healing wound *in situ*, can be augmented or retarded, respectively, by artificial increase or inhibition of the histamine-forming capacity of the growing tissues. In these experiments the histamine-forming capacity was increased by injections of the histamine liberator 48/80, which depletes the skin of its histamine content and concomitantly raises the skin level of histidine decarboxylase. Extracellular histamine, derived from injected 'long-acting histamine', had no detectable effect on growth in healing. It was concluded that only intracellularly formed 'nascent' histamine is active in promoting certain types of growth[2].

Because collagen is a principal component of reparatively growing tissues in skin wounds, and the tensile strength in particular depends on collagen[3], it seemed interesting to determine the rate of collagen formation under conditions of increased histamine-forming capacity effected by injections of 48/80.

Samples of granulation tissue were obtained for study from polyvinyl sponges ('Ivalon') implanted subcutaneously in rats of both sexes from a closed colony bred at our Institute and weighing 200–300 gm. Under ether anæsthesia an incision was made in the mid-line of the back and two sponges were placed under the skin of one side of the back. On the fifth day after the implantation the sponges were removed and collagen content assessed by measuring the constituent amino-acid hydroxyproline[4]. These samples served as controls. About two weeks later each rat received 48/80 (1 mgm./kgm./day) intraperitoneally on three successive days. The activation of histidine decarboxylase resulting from this treatment was discovered by Schayer *et al.*[5], and fully confirmed in this laboratory[1]. On the next day two polyvinyl sponges were again implanted subcutaneously on the opposite side of the back and were removed for examination five days later.

In experiments on 15 rats the formation of collagen was enhanced by the pretreatment with 48/80, as judged from the hydroxyproline content. The granulation tissue formed contained on the average 55 per cent more collagen than the controls, mean ± standard error of mean, 55 ± 9·9 per cent.

These results provide further support of a connexion between certain types of rapid growth and histidine decarboxylase[6,7].

Virginiamycin as an Antibiotic for Poultry Feeds

ANTIBIOTICS are widely used at low levels in commercial feeds to improve the early growth-rate of chickens and turkeys. The amount of response obtained from these drugs appears to be related to the nature and density of the microflora present in the feed and environment[1].

Antibiotics now used in manufactured feeds inhibit both Gram-positive and Gram-negative organisms ('broad spectrum') or, more specifically, the common Gram-positive pathogens ('narrow spectrum'). The new antibiotic, virginiamycin[2–4], is mainly active against Gram-positive organisms, but actually consists of three components having different spectra of activity. To evaluate this antibiotic for use in feed, it was compared with terramycin and zinc bacitracin, which have 'broad' and 'narrow' spectra, respectively, and are typical of the antibiotics used currently in commercial feeds.

(1) Virginiamycin, terramycin and zinc bacitracin were incorporated in the feed at low and high levels and fed to day-old, Cobb's strain, White Rock chicks reared in batteries. Four replicate pens of ten cockerels each were used for all treatments. Chicks were weighed individually at the beginning of the experiment and distributed equally by weight between the various pens. A practical starter-grower feed typical of commercial formulations which more than satisfied the N.R.C. nutritive requirements for chicks[5] was used as the basal ration. Pens were equipped with electrically heated brooders, raised wire floors and fluorescent lights.

At both four and eight weeks, all lots of birds which received antibiotics weighed more than the control lot (Table 1). These differences were significant ($P < 0{\cdot}01$), except for the high levels of terramycin and zinc bacitracin for both periods and the low level of virginiamycin at four weeks.

Table 1. EXPERIMENTAL DESIGN AND RESULTS* ON GROWTH AND FEED EFFICIENCY (F.E.) OBTAINED IN THE THREE EXPERIMENTS

Lot No.	Supplements to basal ration (Amt./ton)	4 weeks Weight (gm.)	4 weeks F.E. (Feed/gain)	8 weeks Weight (gm.)	8 weeks F.E. (Feed/gain)	Mortality (per cent)
	Exp. 1 (Chicks in battery brooders)					
1	None	494^{C}	1·73	$1,254^{C}$	2·20	7·5
2	Virginiamycin					
	4 gm.	$530^{A,B,C}$	1·64	$1,332^{B}$	2·12	2·5
3	9 gm.	559^{A}	1·56	$1,349^{A,B}$	2·00	2·5
4	100 gm.	554^{A}	1·62	$1,422^{A}$	2·04	2·5
5	Terramycin					
	9 gm.	$542^{A,B}$	1·77	$1,369^{A,B}$	2·18	7·5
6	100 gm.	$537^{A,B,C}$	1·74	$1,301^{B,C}$	2·21	10·0
7	Zinc bacitracin

	Exp. 3 (Poults in battery brooders)					
		4·5 weeks		7 weeks		
12	None	589	1·97	$1,335^{b}$	2·04	18·8
13	Virginiamycin					
	10 gm.	660	1·79	$1,416^{a}$	1·88	3·1

* Any two means not having the same capital letter are significantly different; any two means having the same capital letter are not significantly different at the 0·01-level of probability. Small letters likewise indicate significance at the 0·05-level.

Higher levels of terramycin or zinc bacitracin were of not greater value than the lower levels at either interval. Virginiamycin, however, at the 100-gm. per ton-level, was significantly more beneficial ($P < 0{\cdot}01$) than at the 4-gm.-level at eight weeks.

Efficiency of feed utilization was consistently improved by all levels of virginiamycin, and to a lesser degree by the two levels of terramycin and zinc bacitracin. Since the measurements of feed intake were on a pen basis and thus data were limited, too much significance cannot be attached to these differences.

(2) This experiment was carried out using chicks in floor pens which had wood shavings for litter. The basal ration of Exp. 1, modified by adding a coccidiostat ('Nicarbazin', 0·0125 per cent), was used for all treatments. Day-old chicks (25 males and 25 females) were placed in each pen (5 × 9 ft.). Heat for brooding was supplied by infra-red lamps.

Duplicate pens of chicks, allocated as in the previous experiment, received each of the experimental treatments shown in Table 1. Beginning at four weeks of age, a finisher ration containing 18·5 per cent protein was fed. This ration differed from the starter ration only in that 6 per cent of corn replaced an equal amount of soybean oil meal.

At 8 weeks of age the average weights of the birds which received the nine grams per ton level of virginiamycin were greater ($P < 0{\cdot}05$) than those of the control birds. The increased weights of the birds which received four grams per ton were not significantly different from those of the control birds. Birds receiving virginiamycin also had an improved feed utilization; this improvement was about equal for both levels of the antibiotic. Since feed consumption was obtained by pen, it would require more data to be sure of the significance of these findings. It is noteworthy, however, that virginiamycin at all levels in both battery and floor experiments resulted in improved feed efficiency over the controls.

(3) Straight-run Beltsville White and Broad Breasted Bronze turkey poults brooded in batteries were used in this experiment. Duplicate pens of each breed (8 poults per pen) were used for each treatment. The experimental outline and results obtained are shown in Table 1. The addition of ten grams of virginiamycin per ton to a typical practical turkey starter feed (28 per cent protein) elicited a significant improvement ($P < 0{\cdot}05$) in the rate of growth. Livability was also apparently improved.

Summarizing, the battery birds fed virginiamycin at 4, 9 and 100 gm. per ton of feed were significantly ($P < 0{\cdot}01$) heavier at 8 weeks of age than birds fed the control ration, and best results were obtained at the highest level. The floor birds fed virginiamycin at 9 gm. per ton of feed were heavier ($P < 0{\cdot}05$) at 8 weeks than the controls, but not heavier than those which received the 4-gm.-level.

Virginiamycin was comparable to terramycin and zinc bacitracin in its effectiveness on growth, feed utilization and livability. It elicited improvements in rate of growth as it was increased from 4 gm. to 100 gm. per ton of feed. Higher levels of terramycin and zinc bacitracin (100 gm. per ton), however, were not so beneficial as the 4-gm. and 9-gm.-levels, respectively. Feed efficiency was also improved with virginiamycin, with the best utilization at the 9 gm. per ton-level. Since these data were obtained on a pen basis and therefore limited, more repetition would be required to demonstrate the reality of the improvements in feed efficiency observed in these tests.

The results of a preliminary experiment with turkey poults were in agreement with the growth and feed efficiency results obtained with chicks.

We are indebted to Smith, Kline and French Laboratories, Philadelphia, Pennsylvania, for supplying the antibiotics as well as a grant to help finance in part this research.

Proportion of Bromsulphthalein Protein-bound within Incubated Rat Liver Slices

THE behaviour of rat liver slices incubated in media containing bromsulphthalein (BSP) and other dye substances, and the high *in vitro* binding of BSP to plasma proteins and various liver fractions, led Brauer and Pessotti[1] to suggest that uptake of BSP was related to intracellular protein binding.

It is therefore of interest to consider the results of incubation experiments in relation to an equation derived from the Langmuir isotherm[2]:

$$\beta = \frac{\text{bound substance}}{\text{total substance}} = \frac{1}{1 + \dfrac{k}{np} + \dfrac{(D)}{np}} \qquad (1)$$

where k is the dissociation constant, np the receptor concentration and (D) the concentration of unbound substance.

This equation indicates that the proportion bound at equilibrium (β) varies directly with the receptor concentration and inversely with the dissociation constant and the concentration of unbound substance. However, when (D) is small in relation to np the term $\frac{(D)}{np}$ may become negligible, in which case (D) will not affect β significantly.

If adsorption is the only mechanism of uptake by liver slices it follows that experimental values for β should conform to those predictable from equation (1).

The data available from incubation experiments (that is, slice weight and volume of medium, with the quantity of dye in each) is insufficient for direct calculation of β. But if it is assumed that a proportion of the slice volume (F) is available to unbound dye at the same concentration as the medium, then it can be shown that:

$$\beta = \frac{\text{bound dye within the slice}}{\text{total dye within the slice}} = \frac{\text{slice concn.} - F\,(\text{bath concn.})}{\text{slice concn.}} \qquad (2)$$

The value of 0·7 has been used for F. The reasons for this and for the overall assumption will be discussed elsewhere.

Standard incubation experiments were carried out using washed rat liver slices of approximately 0·7 gm. weight and 0·5 mm. thickness, in 3 ml. Krebs–Ringer-phosphate (pH 7·4) containing a known concentration of BSP and maintained at 37° C. Each incubation lasted 30 min., stirring being effected throughout by a vigorous stream of oxygen. Under these conditions no further uptake of dye occurred after 10–15 min. BSP was estimated by diluting a suitable aliquot with 0·5 N ammonium hydroxide and reading against the relevant blank in an absorptiometer.

Alteration of BSP concentration at equilibrium was effected by different initial concentrations. Alteration of the receptor concentration was attempted by: (a) heat denaturation (80° C. for 5 min. prior to incubation), a process believed to reveal further adsorption sites previously concealed within the molecule[3]; (b) the addition of sodium iodipamide (biligrafin) to the medium (2·24 per cent). Biligrafin reduces biliary excretion of BSP in the intact rat, presumably by competing for the same excretory mechanism, and might therefore be expected to occupy sites otherwise available for BSP adsorption.

It was found that initial dye concentrations within the range 25–400 gm./l. did not significantly alter the value calculated for β. Higher BSP concentrations, denaturation and the use of biligrafin all produced changes in the direction expected from equation (1), as shown in Table 1.

Table 1. MEAN VALUE OF β OBTAINED WITH DIFFERENT METHODS OF PROCEDURE

Procedure	Initial BSP concentration (gm./l.)	No. of experiments	$\beta \frac{\text{(Bound BSP)}}{\text{(Total BSP)}}$
Denaturation	0·05	22	0·96 ± 0·016
Standard	0·05	71	0·92 ± 0·025
Biligrafin	0·05	14	0·82 ± 0·056
Denaturation	2·0	10	0·90 ± 0·018
Standard	2·0	25	0·72 ± 0·063
Biligrafin	2·0	10	0·66 ± 0·039

While the application of a simple adsorption isotherm to the system described is a hazardous procedure, the results obtained are not incompatible with the view that adsorption is the main mechanism of BSP uptake in the incubated rat liver slice, and indicate that under favourable conditions liver is able to accept passively a large fraction of the dye presented.

Immunoelectrophoresis with Cellulose Acetate

Previous results with immunoelectrophoresis, using human serum and its equine antiserum, have shown 25 serum constituents[1]. This communication shows that more than 35 precipitin lines may be obtained with an improved method.

The microelectrophoresis apparatus was described previously[2]. A 5-µl. drop of serum is placed at the centre of the cellulose acetate membrane, 22 mm. wide; the buffer used is veronal, pH 8·6, 0·075 ionic strength; the voltage applied is about 8 V./cm. for 120 min. After electrophoresis, a strip of Whatman No. 3 filter paper, 3 mm. wide and 7 cm. long, is placed at each outer edge of the cellulose acetate membrane. To each filter paper strip, 50 µl. of Pasteur Institute equine antihuman serum (lot No. 13,411) are applied evenly. The preparation is left in the apparatus (which is now utilized as a moist chamber) at room temperature, undisturbed for about 16 hr. or

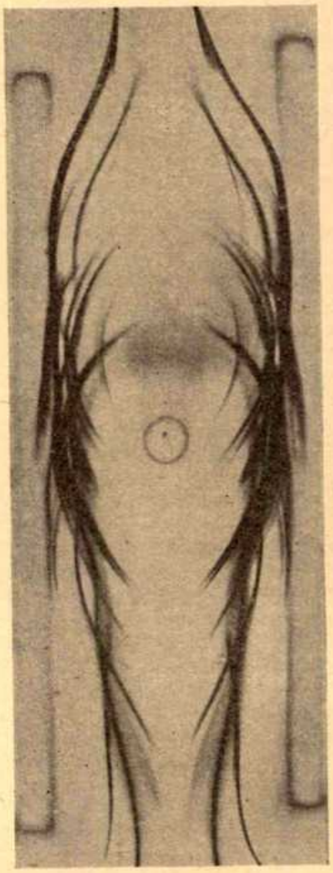

Fig. 1

longer. At the end of the diffusion time the membrane is removed and washed in several changes of physiological saline, finally rinsed in tap water and dried quickly at 110° C. The precipitin lines are stained with ponceau *S* and the background stain removed with 5 per cent acetic acid.

Fig. 1 shows that at least 35 precipitin lines can develop after a 60-hr. immunodiffusion; as many as 28 lines are seen after only 16 hr. Beyond 60 hr. there is no apparent increase in the number of precipitin lines obtained. Reproducibility is good and is mainly dependent on the total amount of serum and antiserum applied, their ratio and the distance between them.

Immunoelectrophoresis is not widely used as an experimental tool mainly because of technical difficulties. This report shows that a very simple method which requires a minimum of technical skill can produce outstanding results.

This work was supported in part by a grant from the U.S. Public Health Service, grant *A*-3774.

Occurrence of Phenylacetylglutamine in Cow's Milk

PHENYLACETYLGLUTAMINE is a normal constituent of human urine[1], but other mammals including the dog, cat, rat, monkey, sheep and horse do not excrete this compound[2]. Phenylacetic acid administered orally to mammals results in the excretion of phenylacetylglycine. The synthesis of phenylacetylglutamine by human tissue has been described by Moldave and Meister[3].

During the course of an investigation on the non-protein-nitrogen fraction of cow's milk by ion-exchange chromatography[4], a fraction was obtained in small quantities which was identified as phenylacetylglutamine. The occurrence of this compound in the milk of any mammal has not to our knowledge been reported previously. Evidence to substantiate the natural existence in cow's milk of phenylacetylglutamine is given here with some characteristics of the compound.

Authentic phenylacetylglutamine was prepared by the method of Thierfelder and Sherwin[5]. Paper chromatography was conducted on 8-in.^{2} sheets of Whatman No. 1 paper using the ascending technique. Desalting of the fractions from the Moore–Stein column was accomplished following the method of Dreze *et al.*[6]. The unknown was isolated from a very small peak falling between urea and aspartic acid in the area normally occupied by methionine sulphoxide. The desalted unknown and authentic phenylacetylglutamine displayed the following properties: ninhydrin-negative on paper; failed to form an *N*-chloro derivative with chlorine gas[7] or with *tert.*-butylhypochlorite[8]; reacted readily with ammoniacal silver nitrate on papergrams; migrated identically in six different solvent systems (the six solvent systems were: $MeOH/H_2O$/pyridine (80 : 20 : 4); *tert.*-$BuOH/H_2O/HCOOH$ (69·5 : 29·5 : 1); 80 per cent EtOH; $EtOAc/MeOH/H_2O$ (50 : 25 : 25); 80 per cent *n*-PrOH; 2-butanone/*tert.*-BuOH/H_2O : diethylamine (40 : 40 : 20 : 4)); in the solvent system 2-butanone/*tert.*-butanol/water/diethylamine (40 : 40 : 20 : 4), two spots were obtained both browning and showing high fluorescence when the paper was heated in an autoclave. Attempts to hydrolyse both samples in 5·7 *N* hydrochloric acid at 110° for 10 days gave no detectable glutamic acid. Partial hydrolysis was effected in 6 *N* sulphuric acid at 180° C. for three days, the glutamic acid being isolated by adsorption on 'Amberlite *IR*-120 (H^+)'.

Isolation of crude phenylacetylglutamine from cow's milk was also accomplished as follows: Six litres of fresh, raw whole milk were concentrated to about 2 litres *in vacuo*, treated with an equal volume of 20 per cent trichloroacetic acid and filtered after 1 hr. The clear filtrate was extracted continuously for 40 hr. with ethyl ether. The serum was adjusted to *p*H 3·1, then extracted continuously for 72 hr. with ethyl acetate. The latter was evaporated *in vacuo*, the residue taken up in 10 ml. water and shaken for 1 hr. with 0·5 gm. charcoal prepared by the Partridge method[9]. The charcoal was filtered, washed with water and the filtrate passed over 'Amberlite *IR*-120 (H^+)'. Elution with 0·1 *N* hydrochloric acid gave crude phenylacetylglutamine having properties identical with the synthetic sample and with the fraction isolated from the Moore–Stein column. On the basis of the material isolated in this manner, it is estimated that milk contains at least 0·1 mgm. phenylacetylglutamine per litre.

PHYSIOLOGY

Formation of Iodinated Protein in Saliva

AFTER intravenous injection of tracer amounts of iodine-131 in the dog, the concentration of iodine in the parotid saliva is 5–20 times that in the plasma. A variable proportion (1–95 per cent, but commonly 10–30 per cent) of this iodine is non-dialysable and is precipitated by common protein precipitants, such as 5 per cent trichloroacetic acid, zinc hydroxide, tungstic acid, and 66 per cent acetone or ethanol. None of the activity in the precipitate is extractable by *n*-butanol, unlike the protein-bound radioactivity of plasma. After hydrolysis of the protein with pancreatin, paper chromatography in a butanol/acetic acid/water system (4 : 1 : 1) revealed radioactivity almost entirely in monoiodotyrosine with only a small amount in diiodotyrosine; there was no sign of labelled iodothyronines. Evidently the organic iodide in saliva is in the form of iodotyrosines linked by peptide bonds into proteins. Formation of protein-bound iodine was completely and immediately prevented by injection of thiouracil or mercaptazole in doses of 5 mgm./kgm. or more, but was not modified by total thyroidectomy.

In vitro formation of protein-bound iodine was readily demonstrated by incubation of freshly secreted saliva with phosphate buffer (*p*H 7·0) containing a tracer amount of iodine-131. Iodine binding was demonstrable within a minute and reached its maximum after 10–30 min. The extent of binding varied between samples obtained at different secretion-rates and in different animals, but was always demonstrable. Binding by the *in vitro* system could be inhibited 90 per cent or more by mercaptazole $2·5 \times 10^{-6}$ *M*, and sulphanilamide, cysteine, mercuric chloride and ferrocyanide 10^{-3} *M*. The considerable capacity of the system was indicated by the lack of depression in the percentage organically bound until the iodide concentration exceeded 10^{-4} *M*. The addition of bovine serum albumin increased the percentage of protein bound iodine by as much as twofold.

In other isolated iodination systems[1] peroxide has been implicated as the oxidant of iodide to an active form. The formation of free peroxide in the saliva system was demonstrated by the formation of purpurogallin on the addition of pyrogallol and horseradish peroxidase. Organic incorporation of iodine was prevented by the addition of 0·5 mgm./ml. of catalase. Attempts to increase incorporation by providing exogenous substrate for the specific oxidases for glucose, xanthine, alanine, tyrosine and tyramine had no appreciable effect. Tyrosine depressed protein-binding probably by acting itself as an iodine acceptor.

Organic iodine was not found in submaxillary saliva of the dog nor in parotid or mixed saliva of man. On the other hand, considerable amounts of organically bound iodine were found in dog gastric juice, bile and succus entericus.

The properties of the *in vitro* saliva system correspond closely to those of homogenates of thyroid and salivary glands of rats[2]. The presence of protein-bound activity mainly in the form of mono-iodotyrosine is similar to the binding in the milk of some species[3]. The biological significance of protein incorporation of iodine in intestinal secretions is obscure. It has been reported[4] that in rats diiodotyrosine is found in the plasma and tissues in undiminished amounts after thyroidectomy and that even some thyroxine is formed. It is possible that formation of organic iodine in the glands of the alimentary canal is of some importance in this process; at least in the dog a considerable proportion of the 'internal' circulation of iodine through the alimentary canal is via organic iodine compounds rather than free iodide.

Effect of Heat on the Kinetic Constants of Myosin–Adenosine Triphosphatase

Nanninga and Mommaerts used the firefly technique for detection of adenosine triphosphate (ATP) in order to establish the binding of ATP to myosin[1]. The addition of creatine phosphate and creatine phosphate transphosphorylase is necessary to counteract the hydrolysis of ATP by the myosin. In this way a maximal binding of 1 mole ATP to 1 mole myosin was established while it was also possible to determine k_1, the kinetic constant of the formation of the ATP–myosin complex, from the initial speed of disappearance of the free ATP as measured from the decrease of the luminescence[2]. The k_1 determination can be done in absence of the rephosphorylating system. The effect of heat inactivation of the myosin on both the k_1 and on the bound ATP was studied. The myosin was 1·31 per cent, dissolved in 0·3 *M* potassium sulphate, 0·01 *M* *tris*-buffer of *p*H 7·0 and was heated for 90 min. at 37° C. Then it was added to the luciferin–luciferase solution at different ATP concentrations. It was found that both k_1 and the bound ATP decrease about sevenfold (Table 1).

Table 1. INACTIVATION OF MYOSIN BY HEATING FOR 90 MIN. AT 37°. FINAL MYOSIN CONCENTRATION, $3·28 \times 10^{-6}$ *M*

	Apparent k_1	ATP bound at $2·0 \times 10^{-6}$ *M* ATP free
Before	$2·32 \times 10^{4}$ sec.$^{-1}$ mol.$^{-1}$	$2·55 \times 10^{-6}$ *M*
After	$0·30 \times 10^{4}$ sec.$^{-1}$ mol.$^{-1}$	$0·35 \times 10^{-6}$ *M*

This result shows that the inactivation is due to a decreased enzyme concentration. Obviously six out of seven myosin molecules lose the power to form a complex with ATP, presumably by oxidation of the SH-group which is involved, as is known from the inactivation by parachloromercuribenzoate, copper and other SH-reagents. The apparent k_1, derived from the initial speed of decrease of the ATP-level[2], decreases seven times, and for the same reason the enzyme substrate complex decreases seven times. The true k_1, however, remains constant.

In separate experiments k_3, the kinetic constant of decomposition of the complex, and K_m, the Michaelis constant, were measured by means of the same technique in the same milieu but with a ten-times lower myosin concentration (compare ref. 2). The constant k_3 follows from the maximal activity, divided by the myosin concentration. After inactivation it appears that K_m is nearly unchanged while k_3 is much smaller. In one series the apparent k_1 was, after 70 min. at 37°, 0·265 times the apparent k_1 before inactivation while the apparent k_3 was 0·233 times the apparent k_3 before inactivation, and K_m 0·92 times K_m before inactivation. The parallel behaviour of k_1 and k_3 must be due to a reduction in the enzyme concentration so that the true k_1 and k_3 remain the same while the enzyme concentration decreases. The alternative possibility of an unchanged formation of enzyme substrate complex with a considerable reduction in its speed of decomposition is therefore ruled out. When k_1' (k_1 after inactivation) divided by k_1 is plotted versus time of incubation, an exponential curve is obtained as $\log k_1'/k_1$ is directly proportional to time of incubation. Since $k_1'/k_1 = M/\Sigma M$ (active myosin divided by total myosin), it follows that $M = \Sigma M \times e^{-kt}$ and $dM/dt = -kM$. In this first-order reaction k is $3·6 \times 10^{-4}$ sec.$^{-1}$ at 37°.

Hypoglycæmia induced by Manganese

PLANT extracts have long been used as home remedies for diabetes mellitus[1-3], and have been investigated for their hypoglycæmic effect[4,5]. However, there has been little experimental or clinical proof of their efficacy[6].

Recently it has come to our notice that infusions of lucerne (alfalfa, *Medicago sativa*) are being used in the treatment of this disease by certain diabetics in South Africa. We have had the opportunity of studying a young male diabetic who gives a marked hypoglycæmic response following the oral administration of an aqueous extract of this plant (Fig. 1). The patient is twenty-one years of age, having been a diabetic for the past seven years. A diabetic glucose tolerance curve has been demonstrated on repeated occasions with fasting blood sugar-levels varying from 150 mgm./100 ml. to 250 mgm./100 ml. He has been treated intermittently with insulin, requiring large doses (100–200 units daily) for even moderately satisfactory control. He himself claimed that lucerne infusions gave better control. He often exhibits the feature of marked hyperglycæmia even when under treatment with insulin with little increase in plasma or urinary ketones. Routine investigations failed to reveal evidence of thyrotoxicosis, Cushing's disease, phæochromocytoma or chronic pancreatitis.

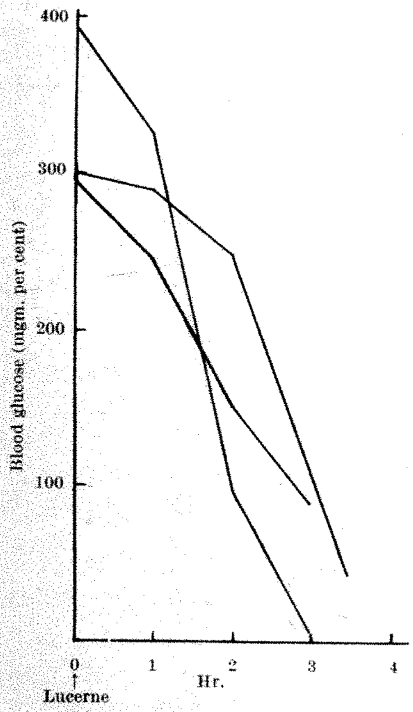

Fig. 1. Blood sugar-levels following the oral administration of lucerne extract

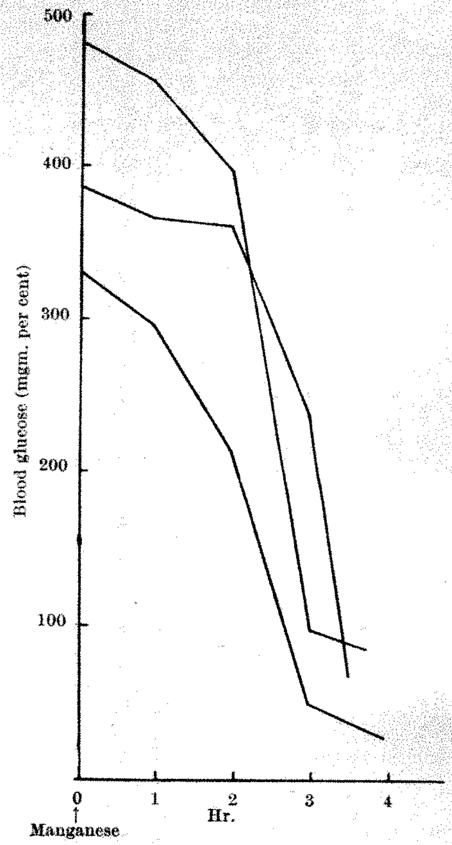

Fig. 2. Blood sugar-levels following the oral administration of 5 mgm. manganese (as manganese chloride)

There was no hypoglycæmic response to the administration of the amino-acid *l*-leucine[7,8]. Parents and sibling have normal glucose-tolerance curves.

Lucerne was noted to contain relatively large concentrations of manganese[9]. Accordingly, manganese as manganese chloride was administered many times orally in doses of 3–5 mgm. and intravenously on one occasion in a dose of 20 mcgm. to the patient. The effect on the blood glucose-level was a consistent fall often to severely hypoglycæmic levels (Fig. 2). Both lucerne and manganese when given orally modified the glucose tolerance curve (Fig. 3).

The oral administration of manganese to four middle-aged diabetics, three juvenile diabetics and one case of diabetes resulting from chronic pancreatitis did not affect the blood sugar-level.

Although manganese is well known to be a component and co-factor in certain enzyme systems including some concerned in the intermediary metabolism of carbohydrates[10], a hypoglycæmic effect of manganese has not previously been reported. The time-interval between administration of manganese and its effect on the blood glucose-level is consistent with the possibility of enzyme activation[10]. Further work on the metabolism of manganese is being done.

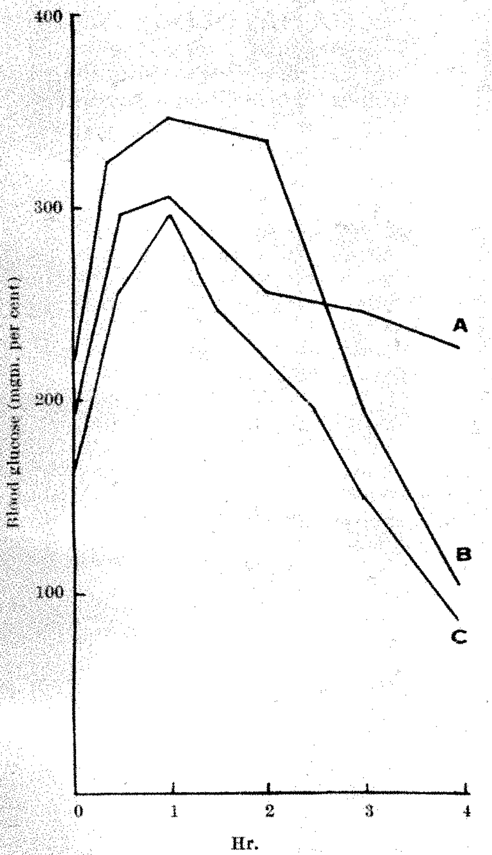

Fig. 3. Glucose tolerance curves: *A*, after 100 gm. glucose orally; *B*, after 100 gm. glucose and lucerne; *C*, after 100 gm. glucose + 5 mgm. manganese (as manganese chloride) orally

In vitro Calcification of Rat Aorta in Serum

Although hydroxyapatite has been identified as a major component of aortic plaques[1], the events leading to its deposition in this tissue are little understood. Recently, we have found that substantial quantities of calcium and phosphate are deposited on to rat aortas during the incubation of this tissue in serum. This finding has provided a useful system for the study of aortic calcification *in vitro*.

Serum and aortas were obtained from mature male Sprague–Dawley rats. Penicillin (5 mgm.), streptomycin sulphate (50 mgm.) and 2 ml. of a carrier-free ^{45}CaCl solution containing approximately 1,200,000 c.p.m. were added to 100 ml. of serum. Each aorta was incubated with 1 ml. of this solution at *p*H 7·4° and 37° C. At various times during the incubation the aortas were removed, washed in several litres of distilled water, air dried, weighed and then placed in 5 ml. of 0·12 *M* hydrochloric acid. Aliquots of this solution were taken for calcium[2], phosphorus[3] and calcium-45 assay.

Following a lag period of approximately 24 hr., there was a marked increase of calcium, phosphate and calcium-45 in the aortas (Fig. 1). Hydroxyapatite was detected by X-ray diffraction in aortas incubated for 72 hr. but not in tissues incubated for 1 hr. About 15 per cent of the calcium initially in the serum was fixed on to the aortas during 72 hr. of incubation. Since incorporation of calcium-45 paralleled the deposition of calcium and phosphate on to the tissues, it was used as a measure of calcification in some experiments.

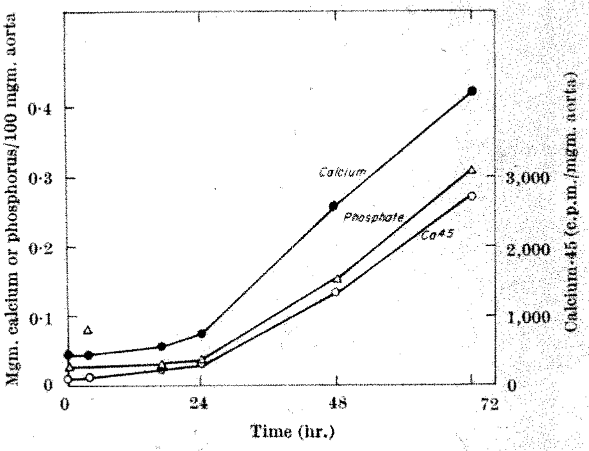

Fig. 1. Uptake of calcium, phosphate and calcium-45 by aorta from serum

Mineralization was accelerated by ageing of serum at 37° prior to incubation or by the addition of alkaline phosphatase (0·5 mgm./ml.) to the serum. These findings suggest the presence in rat serum of labile inhibitors of calcification such as those described by Fleisch and Neuman[4].

In order to identify components in the aorta essential for calcification, aortas were treated with various enzymes prior to incubation. Enzyme digestions were carried out in saline at *p*H 7·4 at 37° for 24 hr. The activities of the enzymes were assayed with 'Azocoll'[5], orcein-impregnated elastin[6] and rat tail tendon. Trypsin, a crude bacterial protease (Nutritional Biochemical Corp.), pronase (*Streptomyces griseus* protease obtained from the California Corporation for Biochemical Research) and three-times crystallized elastase (Worthington Biochemicals Corp.) rapidly digested 'Azocoll'. Only elastase and pronase digested orcein-impregnated elastin. Purified collagenase (supplied by Dr. P. Gallop) digested rat tail tendon.

Treatment of the aortas with collagenase, trypsin, protease and hyaluronidase did not reduce the uptake of calcium-45 by aorta (Table 1). Trypsin and protease increased the c.p.m./mgm. of aorta probably by reducing the amounts of non-essential components. The actual uptake of calcium-45 per aorta in these samples was similar to the 72-hr. control. Elastase and pronase treatment prevented mineralization as indicated by a negligible uptake of calcium-45. These findings suggest that elastin or some other component of the aorta susceptible to both elastase and pronase, but not the other enzymes, was required for mineralization.

Table 1. EFFECT OF ENZYMATIC DIGESTIONS ON THE UPTAKE OF CALCIUM-45 BY RAT AORTAS

Pretreatment	Incubation period (hr.)	Weight (percentage of control)	Calcium-45* (c.p.m./mgm.)
None	1	103	34 ± 0·1
None	72	100	2,865 ± 178
Elastase	72	43	53 ± 7·7
Pronase	72	58·5	308 ± 4·9
Collagenase	72	60·7	2,756 ± 128
Protease	72	65·1	4,100 ± 320
Trypsin	72	62·4	4,750 ± 321
Hyaluronidase	72	102	2,460 ± 73

* Five aortas in each group.

It is evident from these results that the *in vitro* calcification of the aorta is dependent both on the integrity of certain components of the matrix and on alterations in fresh serum. Since aortic mineralization does not ordinarily occur in the rat *in vivo* in the presence of sufficient concentrations of calcium and phosphate to produce *in vitro* calcification and, since calcification is accelerated in aged serum, it seems reasonable to postulate the existence in serum of a potent but labile mechanism for preventing the deposition of mineral in the aorta. It is conceivable that this system is impaired in those conditions where calcified plaques occur *in vivo*. In addition, it is of interest to the general problem of biological calcification that elastin rather than collagen seems to be the component of this matrix essential for mineralization to occur. Other workers[7,8] have implicated collagen in other systems. While the importance of these findings in the formation of normally mineralizing tissues is at present unknown, they do warrant further investigations on a possible role for non-collagenous constituents in initiating mineral formation in the hard tissues.

We thank Drs. A. Posner and D. B. Scott for the X-ray diffraction.

HÆMATOLOGY

Possible Cause of Heinz Bodies in Congenital Heinz-body Anæmia

EXAMINATION of the blood of a ten-year-old girl with congenital Heinz-body anæmia has provided evidence for the presence in the subject's red cells of an unstable hæmoglobin fraction.

The subject, splenectomized eight years previously, yielded the following hæmatological data at the time of examination : hæmoglobin, 8·3 gm. per 100 ml.; packed cell volume, 30·5 per cent; mean corpuscular hæmoglobin concentration, 27·5 per cent; leucocytes, 7,000 mm.[3]; reticulocytes, 30 per cent. Almost every red cell contained one Heinz body or more.

In order to produce Heinz bodies, either *in vivo* or *in vitro*, in red cells previously free of them, it is necessary to overcome the protective action on hæmoglobin of reduced glutathione (GSH). The red-cell GSH concentration normally is maintained through the action of the hexose monophosphate (HMP) pathway, and where this pathway is defective, as in 'primaquine-sensitive' individuals, relatively mild stress on red cells yields Heinz bodies. When the HMP pathway functions normally so that the GSH concentration is maintained, the stress required to produce Heinz bodies is greater.

Table 1

	Normal subjects	Heinz-body anæmia
Reticulocytes (per cent)	0·2–2·0	30
Reduced glutathione (µmoles-SH/ml. RBC)	1·92–3·43	1·90
Oxidized glutathione (percentage total GSH + GSSG)	2·8 –11·2	6·9
Glutathione stability test (percentage of fall)	0–27	22
Glucose-6-phosphate dehydrogenase (ΔOD/min./ml. RBC)	1·40–2·87	3·56
6-Phosphogluconic dehydrogenase (ΔOD/min./ml. RBC)	1·35–2·34	2·91

GSSG, oxidized glutathione; OD, optical density.

In this work the red-cell HMP pathway appeared to function adequately (Table 1) because the concentration of GSH and oxidized glutathione was normal, while glucose-6-phosphate dehydrogenase and 6-phosphogluconic dehydrogenase activities had the high values associated with a young red-cell population[1]. When the cells were stressed by incubation at 37° for 2 hr. with acetylphenylhydrazine according to the GSH stability test of Beutler[2], they showed only the slight fall in GSH that occurs with normal red cells. It appeared, therefore, that the Heinz bodies were not formed through a defect in that portion of the HMP pathway concerned with maintaining an adequate level of GSH.

Erythrocyte catalase has been reported low in a single case of congenital Heinz-body anæmia[3]. Such a defect would permit a plausible explanation for Heinz-body formation which, it is known, may occur through the action of hydrogen peroxide on hæmoglobin. However, in two other cases reported by Schmid *et al.*[4], red-cell catalase was normal. In addition, no Heinz-body formation is noted in the red cells of subjects with acatalasæmia (Takahara, S., personal communication). In the patient, the subject of the present work, the red-cell catalase activity was found to be normal.

The sole anomaly which has been demonstrated in the present work is the formation of a red-brown precipitate when a stroma-free, Heinz-body free hæmolysate of congenital Heinz-body anæmia blood was heated for some minutes at 50° C. Such a precipitate was obtained also when samples of purified patient's hæmoglobin were heated at 50° C. in isotonic phosphate-buffered saline (*p*H 6·5). No such precipitate could be obtained from hæmolysates of normal blood or cord blood, or from blood containing a large number of reticulocytes. Similarly, when purified hæmoglobin from normal blood was heated at 50° C. for the same length of time, no precipitate was obtained. The rate of appearance of the precipitate varied according to the hæmoglobin concentration of the solution. However, the bulk of the precipitate appeared over a short period and further heating produced only small amounts of precipitate such as could be obtained from normal hæmoglobin samples.

Both normal hæmoglobin solutions and those of the subject under study formed some methæmoglobin as a result of the heating procedure. It was found that if all the hæmoglobin in the solutions was converted by $K_3Fe(CN)_6$ into methæmoglobin, then the precipitate was formed more readily on heating at 50° C. and even solutions of normal hæmoglobin under these conditions yielded small amounts of precipitate. On the other hand, the presence of sodium dithionite, which reduced any methæmoglobin to hæmoglobin, suppressed formation of the precipitate. It appeared that in order to produce the precipitate it was necessary for methæmoglobin to be present in the heated solution.

Examination of the precipitate gave evidence that it was soluble in alkaline solution, and at *p*H 10·7 it gave a visible absorption spectrum indistinguishable from that of alkaline methæmoglobin at this *p*H value[5]. In amount, the precipitate accounted for approximately 20 per cent of the total hæmoglobin present. Measurement of the ratio of hæm to globin suggested that the precipitate contained less hæm to globin than does normal unheated hæmoglobin.

It is concluded tentatively that in congenital Heinz-body anæmia the formation of Heinz bodies *in vivo* is the end-result of the presence in the red cells of an unstable hæmoglobin fraction, the instability of which can be demonstrated *in vitro* by heat treatment of solutions of the hæmoglobin.

Myoglobin in the Human Fœtus

Evidence for the presence of a fœtal form of myoglobin in human beings, analogous to fœtal hæmoglobin, has consisted of reported electrophoretic and spectral differences between material obtained from skeletal muscles of infants and that obtained from adults. Electrophoretically, so-called fœtal myoglobin appeared to behave somewhat like fœtal hæmoglobin; however, its absorption spectrum in the visible range showed, unlike either fœtal hæmoglobin or myoglobin from the adult, a "characteristic plateau between the wave-lengths 490–530 mμ at *p*H 8·6" (ref. 1).

Investigations reported here, however, suggest that myoglobin from the fœtus and adult are not distinguishable. Autopsy material of adults and infants, the latter being either premature or full-term, but in no case older than 24 hr., provided the sources of myoglobin. Samples to be compared were prepared simultaneously and by the same technique. Several different methods were used, including that in which the foregoing observations were made[1–4]. The most convenient and reliable technique proved to be a slight modification of that of Theorell and de Duve[2], in which an aqueous extract of muscle was treated with saturated lead subacetate, the supernatant, brought to *p*H 7, was dialysed against 3 *M* phosphate buffer, *p*H 6·6, and the resulting supernatant dialysed against increasingly saturated solutions of ammonium sulphate. Individual cases provided the myoglobin in the adult, whereas in the infant both pooled and individual preparations were studied. These were compared with each other and also with hæmoglobins A and F by means of analytic ultracentrifugation, electrophoresis on various media and at different *p*H's, quantitative amino-acid analysis, spectrophotometry and two-dimensional peptide analysis.

From both infants and adults, myoglobin was obtained which exhibited a single peak on ultracentrifugation with an S_{20} of 2, consistent with its molecular weight. In all cases this myoglobin, whether fœtal or adult in origin, showed the same properties on electrophoresis in the *p*H-range of 6·3–8·6 on paper, starch block and agar gel when care was taken prior to each run to dialyse the preparations against the buffer employed. Total amino-acid composition of myoglobin from the fœtus and adult, determined on a Moore-Stein chromatographic column, and calculated as residues per mole (mol. wt. 16,700) revealed no differences beyond the range of experimental error (Table 1). The absorption spectrum was also identical in the range thought to distinguish two myoglobins. Furthermore, the 'characteristic plateau' could be demonstrated in myoglobin from either source simply by dilution (Fig. 1). Two-dimensional peptide patterns produced by trypsin and trypsin plus chymotrypsin digestion were indistinguishable within the

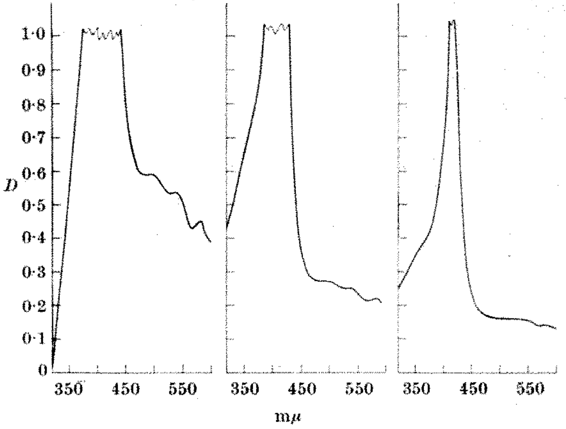

Fig. 1. Absorption spectra at *p*H 8·6 of metmyoglobin from fœtal or adult source at various dilutions: (left) 120 mgm. per cent; (centre) 60 mgm. per cent; (right) 30 mgm. per cent. The latter has been described as 'characteristic' for myoglobin from the fœtus only

Table 1. Amino-acid Composition of Human Myoglobin (No. residues/molecule)

Amino-acid	Adult	Fœtus	Amino-acid	Adult	Fœtus
Alanine	14	14	Serine	6	6
Glycine	17	17	Methionine	2	2
Valine	9	9	Arginine	2	2
Leucine	17	17	Histidine	8	8
Isoleucine	7	7	Lysine	15	15
Proline	6	6	Aspartic acid	13	12
Phenylalanine	7	6	Glutamic acid	18	16
Tyrosine	2	2	Threonine	5	5

Results of 17-hr. hydrolysis of myoglobin from the adult and fœtus. Tryptophan was not determined. Cf. Rossi-Fanelli *et al.* (ref. 5).

limits of the technique used[6] (Fig. 2). It is worth noting that crystals of myoglobin obtained from adult and fœtal sources also appear to be identical[2,3].

These results suggest that myoglobin from the human fœtus is indistinguishable from that of the adult, and that previous observations may have been due both to its presence in small amounts in the fœtus and the difficulty in separating it from fœtal hæmoglobin.

I thank Drs. C. B. Anfinsen, R. W. Canfield and H. Metzger, along with Mrs. M. Thoren, for advice and help in this work, and Dr. J. Bolveri for providing fœtal muscle.

A Rapid Screening Dye Test for the Detection of Glucose-6-Phosphate Dehydrogenase Deficiency in Red Cells

Motulsky *et al.*[1] have reported the adaptation of the spectrophotometric glucose-6-phosphate (G6P) dehydrogenase estimation[2] to a visual qualitative test; the rate of decolorization of incorporated brilliant cresyl blue, acting as an electron acceptor, enabled red cells with normal and deficient enzyme activity to be distinguished (see Vella[3] for description). Some brands of brilliant cresyl blue were found to be far more effective as electron acceptors than others, requiring standardization of the decolorization time for each particular dye to assess normal enzyme activity[4].

The development of a screening test, adapted from a general colorimetric assay for dehydrogenases[5], revealed certain advantages. In the conversion of glucose-6-phosphate, in the presence of triphosphopyridine nucleotide (TPN), by glucose-6-phosphate dehydrogenase, to 6-phosphogluconate and TPNH, phenazine methosulphate (PMS) is used as the electron carrier between TPNH and 2,6-dichlorophenol-indophenol (DPIP) or 2,6-dichlorophenol-indo-*o*-cresol (DPIC):

$$\text{TPNH} + \text{PMS} \longrightarrow \text{TPN} + \text{reduced PMS}$$

$$\text{Reduced PMS} + \underset{\text{(blue)}}{\text{DPIP}} \longrightarrow \text{PMS} + \underset{\text{(leucobase)}}{\text{reduced DPIP}}$$

The rate of decolorization of DPIP is thus a measure of the erythrocytic glucose-6-phosphate dehydrogenase activity.

Water, 1 ml., was placed in 75 × 10 mm. test tubes, and 0·02 ml. well-mixed blood with a packed cell volume of 40–50 per cent added from a hæmoglobin pipette (with suitable refrigeration, oxalated or heparinized samples were tested satisfactorily 4–5 days after sampling, while blood preserved in acid citrate dextrose showed little increase of time after 10–14 days). The tube was well mixed to hæmolyse the red cells. The dye reagent, 0·5 ml., was added and mixed. The dye solution consisted of 0·74 M *tris* buffer, pH 8·0, containing 2,6-dichlorophenol-indophenol, 0·5 mM, that is, 14·5 mgm. per cent (the optimal pH for red cell glucose-6-phosphate dehydrogenase activity showed a broad peak between 7·5–8·4); TPN (2·3 mgm./ml., about 3 mM, stored in deep-freeze); G6P (15·2 mgm./ml. anhydrous or 17·9 mgm./ml. Boehringer, 50 mM, stored in deep-freeze); and PMS (2 mgm. per cent, fresh weekly and stored refrigerated in the dark)—in the proportion of 8 : 0·5 : 0·5 : 1, prepared fresh before use. The mixture was overlaid with mineral oil and stood at room temperature or incubated at 37° C. The time was noted for decolorization to a red-yellow end-point (two absorption bands of oxyhæmoglobin); afterwards, the colour changed to red-purple (single absorption band due to reduced hæmoglobin).

The substrate and co-enzyme concentrations have been adapted from optimal amounts used in the quantitative enzyme assay[6]; however, since TPN was regenerated in the system, the quantity used could be reduced. While increasing or decreasing the dye content altered the decolorization times proportionately, the amount of DPIP used was best suited to the appearance of the colour change. As the decolorization time was only slightly less at 37° C. than at room temperature, the latter method could be most usefully adopted in small laboratories or in the field. The use of phenazine methosulphate to mediate electron transfer between TPNH and DPIP obviates the use of diaphorase required in colorimetric assays of dehydrogenases. Phenazine methosulphate is an oxidation-reduction indicator (E = + 0·080), but could not be used by itself, because of its pale yellow colour, as a visual indicator. On the other hand, omission of PMS resulted in the DPIP being decolorized very slowly, namely, 4–6 hr., indicating that PMS acted as a highly active non-enzymatic agent for electron transfer.

Using the above system, decolorization times ranged from 5 to 20 min. for 280 subjects shown to have normal glucose-6-phosphate dehydrogenase activity by the quantitative Glock and McLean assay[6], and 1½–3½ hr. for 40 samples with deficient red cell enzyme activity. Comparative tests with the most active brands of brilliant cresyl blue, using similar concentrations of substrate, co-enzyme and dye, gave end-points of 30–75 min. in red cells with normal enzyme activity and 2–8 hr. in cases of deficient activity on incubation at 37° C. and considerably longer times when tested at room temperature. A difficulty encountered with the brilliant cresyl blue test has been to assess the enzyme status of samples decolorizing in 75–120 min. The phenazine methosulphate test gave a clearer separation between red cells with normal enzyme activity and cases with inherited or acquired glucose-6-phosphate dehydrogenase deficiency; further, the phenazine methosulphate test was more successful in detecting the heterozygous female with an intermediate enzyme activity in the sex-linked inherited glucose-6-phosphate dehydrogenase deficiency[7].

To date, no false results have occurred in more than 500 samples checked in parallel with the quantitative glucose-6-phosphate dehydrogenase assay[6], methæmoglobin reduction test[8], and reactions (Heinz body production[9], glutathione instability[10]) that are associated with erythrocytic glucose-6-phosphate dehydrogenase deficiency. Where there is marked anæmia, an appropriately greater volume of blood should be used to avoid the possibility of a false positive. Caution in interpretation may be required in blood specimens showing a reticulocytosis, where the higher enzyme content of young red cells[11] may mask a virtual deficiency; and in conditions of leucocytosis and leukæmia—here packed red cells should be tested after removal of the buffy coat.

PATHOLOGY

Incorporation of Host Nuclear Materials into Transplanted Tumour Cells in Surgical Wounds

AREAS of acute inflammation contain extracellular deoxyribonucleic acid (DNA) derived principally from dead leucocytes[1–3]. It has been suggested that components of this DNA may be re-utilized by proliferating cells; but direct evidence for this concept has not been reported[3,4].

Evidence that DNA components can be re-utilized following death of a cell was obtained in the work reported here by showing that proliferating tumour cells incorporated tritiated thymidine into their nuclei following transplantation into an animal which had been given this labelled nucleoside 24 hr. previously. The experimental design was based on the following considerations: (1) tritiated thymidine is incorporated exclusively into the DNA of proliferating cells and remains within the cell until its death or division when distribution of label to daughter cells occurs[5]; (2) tritiated thymidine is available for utilization for only a short period (1–2 hr.) following its administration to an animal, being either incorporated into DNA or converted into non-utilizable end products which are excreted[6]; (3) the tritium label in the thymidine base is stable and, because it is a low-energy β-emitter, permits localization at the cellular level by autoradiography[5]; (4) transplanted tumour tissue can be distinguished from host tissue in histological preparations.

Each of 21 *DBA* mice received two intraperitoneal injections 12 hr. apart of 25 μc. each of tritiated thymidine. Twenty-four hours after the last injection a square of viable sarcoma 180 tissue, measuring approximately 3 mm. in diameter, was transplanted into a fresh surgical wound in each mouse. An incision was made in the abdomen down to, but not including, peritoneum and the transplant was placed in this incision. The wound was closed with two interrupted silk sutures. These procedures were carried out under light ether anæsthesia. Following this, three mice were killed at intervals of 24, 48, 72, 96 and 120 hr. Sections of the wound and tumour were taken for routine histological and autoradiographic examinations. Tissues were fixed in 10 per cent buffered formalin. Autoradiographs were prepared with '*AR* 10' stripping film and were exposed for four weeks prior to development.

After 24 hr. a marked acute inflammatory reaction was seen at the site of implantation. Roughly 20 per cent of the infiltrating neutrophiles and mononuclear cells were labelled. Areas of karyorhexis were present and showed extracellular radioactive material. Tumour cells did not contain any label at this time. A few fibroblasts were labelled.

Sections of tissue taken after 48 and 72 hr. also showed marked acute inflammation with an abundance of labelled leucocytes; there was more karyorhexis and considerable extracellular label over nuclear debris. Most important, a small number of tumour cells showed 5–10 grains over their nuclei. After 96 and 120 hr. fairly large nodules of tumour tissue were seen with focal inflammation and adjacent areas of fibroplasia. The percentage of labelled leucocytes was less than that seen earlier. After 120 hr. the greatest degree of labelling in tumour cells was seen, although only a minority of tumour cells were labelled even at this time; most of the labelled tumour cells were of a less bizarre type and were scattered throughout the tumour (Fig. 1). A large number of proliferating fibroblasts showed moderate labelling.

This work indicates that some constituent of DNA is liberated from dead leucocytes in an area of surgically produced inflammation which is then incorporated into proliferating tumour cells and probably into fibroblasts. The precise nature of the component of DNA thus liberated and the extent to which it is re-utilized cannot be determined on the basis of the present observations. In view of recent investigations concerning the incorporation of tritium-labelled DNA into HeLa cells in tissue culture, the possibility exists that relatively large fragments of the DNA molecule can be utilized by a growing cell population[7].

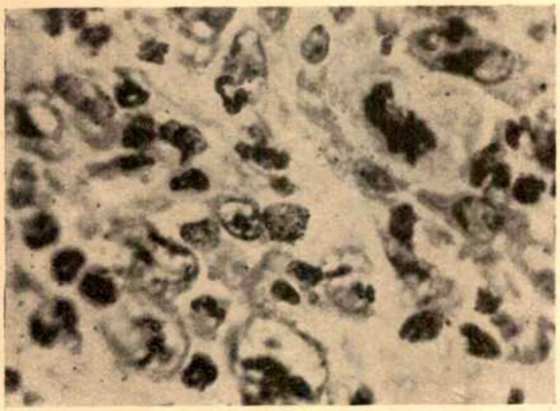

Fig. 1

Previous observations made in connexion with studies of normal wound healing have led to the speculation that availability of DNA or its breakdown products from areas of inflammation may influence the growth-rate of tumours. DNA components from leucocyte nuclear debris may be regarded as constituting a temporary metabolic pool. This work has shown that, locally, transplanted tumour cells and probably proliferating fibroblasts can incorporate the DNA components from this pool.

Previous work on the incorporation of tritiated thymidine by fibroblasts, ascites tumour cells, and osteoblasts has been reported; but in all these studies thymidine was injected simultaneously or after the wounding or tumour transplantation and therefore the probability of primary or direct incorporation of the labelled material by the fibroblasts or tumour cells makes any conclusions about re-utilization of DNA unfeasible[8-10]. Attempts at demonstrating re-utilization of labelled adenine by sarcoma 180 cells transplanted into mice by a trochar have met with limited success and have led others to the view that re-utilization does not occur "to any great extent"[11]. However, results supporting this conclusion were obtained from analysis of tissue homogenate and is difficult to evaluate on a cellular basis.

Intracellular Phase of Existence of Lymphocytes during Remission of Acute Lymphatic Leukæmia

THAT lymphocytes may be found inside other larger cells is now well established[1,2]. In these laboratories this phenomenon has been observed in material examined by tissue culture methods from many patients suffering from Hodgkin's disease and the other malignant reticuloses. Further work[3] has shown that in certain cases of acute leukæmia, the leukæmic cells may be difficult to maintain alive by themselves but can be maintained for long periods in association with established living cell sheets, for example, thyroid cells or embryonic tissues.

A feature of acute leukæmia in children is the occurrence of remissions during which it may be impossible to detect any sign of the disease process by conventional diagnostic methods. In one such case, a boy aged four, in remission from acute lymphatic leukæmia, bone marrow was examined by the 'slide-cell'[4] technique as well as by conventional stained films. The films showed merely a very cellular marrow with an excess of nucleated red cells (Fig. 1). The 'slide-cell' preparation after 24-hr. incubation confirmed this finding, but after 48 hr. when the dying cells had been washed away on replacing the culture medium many large reticulo-endothelial macrophages were found each containing many small active lymphocytes (Fig. 2). It is possible that an intracellular phase of the leukæmic cells may therefore occur during the remissions of acute leukæmia.

Glucose-6-Phosphatase, Glucokinase and Selenium

Rats fed a diet containing yeast as the sole source of protein—the 'necrogenic yeast diet' of Lindan and Himsworth[1]—develop, after a latent period of varying length, a fatal liver necrosis. While the phenomenon itself is well known and has been extensively studied, there is little information available concerning the changes which take place during this period of latency, and which culminate in the rather sudden onset of liver necrosis. It is, therefore, of interest to see that Schwarz, who has extensively studied the problem of dietary liver necrosis, considers that there exists, in the animal fed the necrogenic yeast diet, a "lack of glyconeogenesis"[2].

In recent years it has been shown[3-5] that selenium, added in trace amounts to the necrogenic yeast diet, prevents the onset of liver necrosis, probably by relieving a true deficiency[6]. If, therefore, the defect in gluconeogenesis in the rat liver is in any way causally associated with the phenomenon of liver necrosis, it is reasonable to assume that the necrosis-preventing effect of selenium would be reflected in, or paralleled by, changes in gluconeogenesis. Since it has become apparent that alterations in the rate of gluconeogenesis by the liver are often associated with corresponding alterations in the activity of glucose-6-phosphatase[7], we considered it of interest to study the effect of supplements of selenium on the activity of this enzyme in the liver of rats fed the necrogenic yeast diet, and to combine this investigation with a simultaneous study of the liver glucokinase of these experimental animals. Although little work has as yet been carried out on changes in the activity of the latter enzyme, due to the difficulties associated with its assay, it might be expected that alterations in the activity of glucokinase would be associated with gluconeogenesis, in the sense that an increase in gluconeogenesis would be associated with a decrease in glucokinase activity. Di Pietro and Weinhouse[8] have, for example, shown that the activity of liver glucokinase was decreased in the starved rat, and in rats made diabetic by alloxan. These considerations, therefore, prompted us to undertake the following experiment.

Male Wistar rats, weaned on the twenty-first day of life, the first day of the experiment, were fed the necrogenic yeast diet of Lindan and Himsworth[1]. On the eighteenth day of the experiment the animals were divided into two groups each. One group was given the necrogenic yeast diet as before, but their litter-mates were now fed the necrogenic diet supplemented with sodium selenite at a level of 0·00002 per cent. All animals were killed six days later by a blow on the head. The livers were rapidly removed, weighed, minced, and aliquot portions were taken for determinations of total nitrogen, glucose-6-phosphatase activity and hexokinase activity. Total nitrogen was determined by digestion according to Kjeldahl, followed by Nesslerization. The glucose-6-phosphatase was assayed by measuring the release of inorganic phosphate on incubation of glucose-6-phosphate and of the liver homogenate at a *p*H of 6·5, at a temperature of 37° C. Glucokinase was assayed by a method, similar in principle to the method of Di Pietro and Weinhouse[8], the details of which will be published at a later date[9]. It is sufficient to say that a homogenate of liver was incubated for 30 min. at 37° C. to decrease endogenous glucose-6-phosphate, and then centrifuged to remove coarse particles. The supernatant was incubated at 37° C. with a mixture of *tris* buffer (*p*H of 7·4), magnesium chloride, glucose, adenosine triphosphate, a large excess of glucose-6-phosphate dehydrogenase and triphosphopyridine nucleotide (TPN). The glucokinase present in the liver supernatant catalyses the production of glucose-6-phosphate which, under these conditions, is immediately oxidized by the TPN. The reduction of TPN was followed by means of a spectrophotometer and the rate of this reaction was taken as a measure of the glucokinase activity. In the present method for the assay of glucokinase, the necessity of high-speed centrifugation of the liver homogenate, recommended by Di Pietro and Weinhouse[8], was obviated by the presence of large amounts of glucose-6-phosphate dehydrogenase. The comparatively small amounts of glucose-6-phosphatase present in the liver supernatants could be shown to produce only negligible errors in the determinations of glucokinase.

Table 1. EFFECT OF SUPPLEMENTS OF SELENIUM ON THE ACTIVITY OF GLUCOSE-6-PHOSPHATASE AND GLUCOKINASE IN THE LIVER OF RATS

Necrogenic yeast diet	Selenium	No selenium
No. of rats	8	9
Weight of rat (gm.)	44·4 ± 1·7	41·5 ± 1·1
Weight of liver (gm.)	2·47 ± 0·10	2·14 ± 0·07
Percentage of nitrogen in liver	2·53 ± 0·15	2·47 ± 0·07
Glucose-6-phosphatase μM./hr./mgm. liver nitrogen	20·5 ± 2·2	21·7 ± 1·3
Glucokinase μM./hr./mgm. liver nitrogen	2·72 ± 0·21	3·17 ± 0·14

The results of this experiment are presented in Table I. It can be seen from these data that the administration of selenium over a period of six days to rats previously fed the deficient diet for 17 days had little effect on the body-weight, the weight of the liver or the level of nitrogen, glucose-6-phosphatase or glucokinase of these livers. A lower level of glucokinase was found in the rats treated with selenium, but this difference is not significant at the 0·05 level. Similarly, no significant differences are found when the enzymatic activities are expressed per mgm. of liver (wet weight), or per 100 gm. of body-weight. It could be argued, of course, that both the period of depletion of, and the period of supplementation with, selenium may not have been sufficiently long to demonstrate clearly any possible effects. Since, however, the average survival-time of weanling rats on this necrogenic diet is only approximately 30 days, it is questionable whether a prolongation of either of these periods would have demonstrated an additional effect. In the light of the results presented here we, therefore, conclude that selenium, under the experimental conditions described, has no effect on the activity of glucose-6-phosphatase and glucokinase. While we cannot exclude the defect in gluconeogenesis stated by Schwarz to develop during the latent interval before the onset of liver necrosis, we have not been able to demonstrate this defect by the indirect means used here. The failure of selenium, however, to produce any changes in the enzymatic activities studied here suggests that its main effect in the prevention of liver necrosis probably will have to be looked for in other directions.

IMMUNOLOGY

Congenital Syphilis and the Timing of Immunogenesis in the Human Fœtus

RESULTS obtained in the study of immunological tolerance have lent credence to the generalization that the mammalian fœtus is incapable throughout gestation of responding specifically to an antigenic stimulus. Data are accumulating, however, which suggest that in at least some mammalian species the fœtus may be able to mount an immunological response. Schinckel and Ferguson[1] demonstrated that the fœtal lamb is capable of rejecting adult skin homografts in a manner comparable to that of the adult sheep. Fennestad and Borg-Petersen[2] reported that fœtal calves infected *in utero* with *Leptospira* could be shown at birth to have a higher anti-*Leptospira* titre than their mothers. Uhr[3] has observed that fœtal guinea pigs are capable of an active production of delayed hypersensitivity against protein antigens. We have observed[4], following injection of antigenic stimuli into the fœtal lamb, the production of γ-globulin and of antibody by the normally agamma-globulinæmic fœtus. Finally, the older literature[5] contains a number of references to the occurrence in congenital syphilis of Wassermann titres higher in the new-born's serum than in that of the mother, and to positive Wassermann titres in the child's serum in the presence of negative maternal serology. We may anticipate that future investigations will establish the earliest time of appearance of immunological differentiation in some of these species.

Data on the timing of immunogenesis in man will be more difficult to attain. It has generally been considered that the new-born human reacts poorly, if at all, to the common pædiatric immunizations, although this has been open to question[6]. On the morphological level the absence of plasma cell development in the human fœtus[7] and in the normal new-born[8] has been cited as evidence for immunological immaturity at these age periods. Bridges *et al.*, in an examination of the normal offspring of an agamma-globulinæmic mother, have shown that only after the second month of life did the new-born produce antibodies and γ-globulin, with the concurrent appearance of plasma cells. I would make the point, however, that a functionally and anatomically immature lymphoid system and the absence of plasma cells in the human fœtus may represent the high state of protection from antigenic stimulus conferred on the fœtus by the placenta, and may reflect the time required to mobilize a response to the first stimuli rather than being indicative of the existence of the fœtus in an immunological 'null' period.

Lukes and I have recently had the opportunity[9] to re-examine the histopathology of congenital syphilis in the human stillborn fœtus, and observed a rather consistent pattern of mature plasma cells and plasmacytoid cells associated with the inflammatory lesions in the fœtus. The youngest case in which we had an opportunity to observe good plasma cell development was in a 1,210-gm. stillborn. Based on recent concepts of the immunological role of the plasma cell in response to antigenic stimulus, it seems not unreasonable to conclude that the stimulus provided by the *Treponema pallidum* in these fœtuses has induced the morphological analogue of an active immunological response.

The morphological response of the human fœtus to stimulus during congenital syphilis infection may not only furnish an indication of fœtal ability to respond immunologically but may also provide a clue to the timing of immunogenesis in the fœtus. Such data will not be obtainable experimentally, and will have both practical and theoretical interest.

It is generally agreed that congenital syphilis does not occur much before the sixth month of gestation. Table 1 indicates the age incidence of stillbirth from diagnosable congenital syphilis. It has been considered that this age distribution is attributable to the development of the ability of the placenta to transmit the organism from mother to fœtus. Such transplacental transmission has been assumed to be impossible during the earlier stage of gestation. The incidence of congenital syphilis with gestational age may be indicative, however, of the timing of development of fœtal ability to respond to stimuli. A fœtus younger than 5 or 6 months might not yet have matured its ability to respond to a stimulus with the production of antibody, of γ-globulin, or with the corresponding morphological analogue of a mature reticulo-endothelial system able to mount a chronic inflammatory response, and able to differentiate plasma cells. In the absence of its ability to respond to the *Treponema*, early infection might not induce sufficient embarrassment to cause death and expulsion of the fœtus. (It is conceivable that a heavy infestation of the tissues by *T. pallidum* during early fœtal development may result in an interference with normal parenchymal differentiation without inflammation, which may account for the interstitial fibrosis of the liver, for example (Smetana, H. F., personal communication). Only after the genesis of fœtal ability to respond to the treponemal stimulus would one see the inflammatory response, as an attempt to end the previously unmolested existence of the invading pathogen within its tissues. Stowens[10], in fact, cites the rare instance of very young fœtuses showing positive stains for *Treponemae* in the absence of inflammatory response—a very suggestive observation.

Table 1. AGE INCIDENCE OF STILLBIRTH WITH CONGENITAL SYPHILIS *

Gestational age (month)	Incidence (per cent)
5	1·6
6	7
7	20
8	24
9	22
10	19
Term	5·3

* Data taken from Rietschel (ref. 11).

Concomitant with the response of the fœtus there might develop active lesions suggestive of a mechanism for host embarrassment and death. The appearance of plasma cells in association with the inflammatory response of the fœtus suggests a relationship between the timing of specific immunogenesis and the maturation of other less specific participating reticuloendothelial elements. We may, therefore, consider the possibility that the earliest occurrence of inflammatory response and plasmacytosis in congenital syphilitic fœtuses does not represent the timing of initial infection of the fœtus, that is, of the placental transmission of the organism. Rather, this may be an indication of the timing of maturation of fœtal ability to respond to the stimulus with differentiation of immunologically active cells.

From the available data we may tentatively assign approximately the sixth month of gestation as the time of observable maturation of host response and of immunogenesis. I would emphasize two points: first, that at least the final stages of immunological differentiation may proceed only in response to an exogenous stimulus, and secondly, that stimuli may plan a 'non-specific' part in the induction of a more mature lymphoid tissue able to provide a more fertile ground and a greater supply of undifferentiated stem cells on which the specific antigenic stimulus may then operate.

Antibody Production *in vitro* by Means of a New Perfusion Chamber

THE *in vitro* production of antibodies by explanted tissues or cells has been demonstrated by numerous workers. With a few exceptions, most of the reports have utilized qualitative or semi-quantitative methods to assay the antibody-levels. In those studies in which the investigators were able to measure the amount of antibody produced, either by isotopic techniques[1–3], or quantitative precipitin assay[1,4], the production of antibodies *in vitro* was of relatively short duration.

This communication describes a perfusion apparatus encompassing Trowell's principle of maintaining the tissues near the surface of the medium[5] as well as certain aspects of Steiner and Anker's chamber[4], in

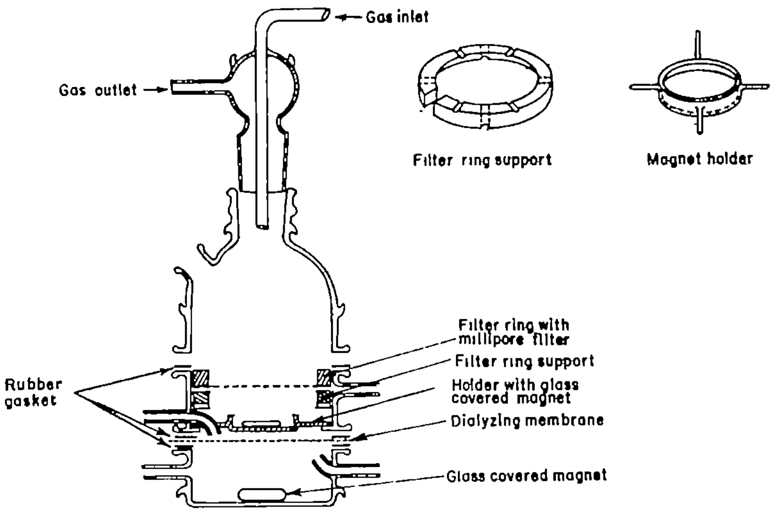

Fig. 1. Cross-section of the perfusion chamber and inserts

which the dialysable metabolic products were constantly removed.

The perfusion apparatus (Fig. 1) is divided into three chambers: (1) Upper chamber: various environmental gas phases can be maintained and the gas mixtures can be regulated to flow at any desired rate through the chamber. (2) Middle chamber: this contains a well consisting of a plastic ring to which is cemented a 'Millipore' filter. Tissues are explanted on the filter within the well. The pore size of the filter can be regulated so that the cells are contained but the fluids can pass freely to and from the culture. The well is supported by a glass ring which maintains the culture near the surface of the medium. Medium can be pumped through the chamber at any desired rate and mixed continuously by means of a glass-enclosed magnet. (3) Lower chamber: the lower chamber is separated from the middle chamber by a dialysing membrane. Medium of the same composition flows through this chamber at an independently regulated rate and is mixed by a stirring magnet. The apparatus can be autoclaved without the Millipore filter portion, which is sterilized by ultra-violet and inserted aseptically.

Advantages of this apparatus are that a relatively large amount of cells or tissues can be maintained in a functioning state for long periods of time. The culture can be supported near the surface of the medium; dialysable and non-dialysable metabolic products removed at any desired rate; and a given concentration of nutrients maintained within the chamber. Moreover, it offers a dynamic system for the study of physical and chemical influences on cellular metabolism and growth.

Table 1. Composition of Medium

1-Amino-acids	Mgm./l.	Carbohydrates	Mgm./l.
Arginine	168	Glucose	4,500
Cystine	96		
Glutamine	293	Salts	
Histidine	84	NaCl	6,800
Isoleucine	210	KCl	400
Leucine	210	$CaCl_2$	200
Lysine	292	$MgSO_4.7H_2O$	200
Methionine	60	$Fe(NO_3)_3$	0.1
Phenylalanin	182	$NaH_2PO_4.H_2O$	138
Threonine	190	$NaHCO_3$	3,700
Tryptophan	32		
Tyrosine	145	Miscellaneous	
Valine	187	Penicillin	0 5
Vitamins		Phenol red	20
Choline chloride	4	Insulin	1 82
Nicotinamide	4	Homologous rabbit serum (28 per cent)	
Calcium pantothenate	4		
Pyridoxal hydrochloride	4		
Riboflavin	0·4		
Thiamine	4		
-Inositol	7		
Folic acid	4		

The use of this apparatus is illustrated in the following experiment in which antibody was produced in sufficient concentration so that quantitative precipitin tests could be used for antibody estimation.

An adult rabbit was immunized with hæmocyanin (*KLH*) obtained from the giant keyhole limpet. The animal was immunized by intravenous injections spaced two months apart. After an additional rest period of three weeks, the rabbit was given 10 mgm. *KLH* intravenously on two consecutive days and was killed two days after the last injection. The spleen was dispersed in 20 ml. of a modified Eagle's medium (Table 1) using a stainless steel screen, centrifuged at 1,000*g* for 3 min., and resuspended in the modified Eagle's medium; 0·9 ml. of packed spleen cells were explanted in the middle chamber, which contained 40 ml. of the medium. Incubation was at 37° C. in an atmosphere of 95 per cent oxygen and 5 per cent carbon dioxide. Changes of fluid were made at daily intervals (except the ninth day when two samples were taken) by removing 10 ml. of medium and immediately adding 10 ml. of fresh medium. Approximately 50–75 ml. of medium flowed through the bottom chamber each day.

Microquantitative precipitin tests were carried out using a modification of the method described by Lanni and Campbell[6]. The precipitin tests were made at *p*H 6·5 using a cacodylate buffered saline ($\mu = 0{\cdot}15$) as diluent[7].

The calculation of net cumulative amount of antibody was made using the equation:

$$AB = V_t C_n = \sum_{i=1}^{n-1} V_{si} C_i$$

AB, net cumulative amount of antibody; V_t, total volume in middle chamber; C_n, concentration of antibody on day '*n*'; V_s, volume of sample removed.

The results (Fig. 2) demonstrate a rapid rise in the amount of antibody in the chamber during the first four days, a levelling off during the next four days, and then a decrease in both the antibody concentration in the chamber and the net cumulative amount of antibody. Precipitating antibodies were demonstrable for 13 days. The net total production of antibody approximated 4·5 mgm. of protein per ml. of packed spleen cells. The possibility that fluctuations of the antibody-levels are the result of degradation or inactivation of the antibody produced is under investigation. Further work is also in progress endeavouring to establish optimal conditions for antibody production utilizing the perfusion chamber.

This investigation was supported in part by the National Institutes of Health, U.S. Public Health Service.

I thank Dr. Dan H. Campbell, in whose laboratory the apparatus was devised. I also thank Drs. J. S.

Use of a Non-persisting Dye for demonstrating Local Anaphylaxis

The introduction by Ramsdell[1] of the use of vital dyes for demonstrating increase in capillary permeability in local anaphylactic reaction opened up a whole new field of investigation of this phenomenon in experimental animals[2,3]. The characteristics required in dyes for such purpose are low toxicity, retention within the blood vessels for a reasonable period and the ability to diffuse out with the blood plasma when a local increase in capillary permeability permits escape of the latter into the tissues.

Emphasis heretofore in local anaphylactic studies has been on dyes which persisted in the animal body for considerable periods of time. Such dyes, however, diffuse through the capillary walls in a matter of hours to produce an undesirable, persisting coloration of the entire skin of the animal.

We have now investigated the use of a non-persisting dye, 'Coomassie Blue', in cutaneous and pinnal[4,5] anaphylaxis. This dye does not produce generalized skin coloration, and we have found it to present distinct advantages over persisting dyes for certain types of investigations. At the present time we wish to report the characteristics of the dye and make available injection schedules for mice and guinea pigs.

The dye we have found suitable for injection is 'Coomassie Blue Medical' (Imperial Chemical Industries, Ltd.). This we have made up in saline as a 1·75 per cent solution for use in guinea pigs, the dosage being 0·1 ml. per 100 gm. body-weight intravenously, or 2·0 ml. per 350–400 gm. animal intraperitoneally. For mice we have found a 0·5 per cent solution of coomassie blue in saline more practical. For an 18–25-gm. mouse 0·15 ml. is used for intravenous injection, or 0·25 ml. for intraperitoneal injection.

Intravenous injections are given simultaneously with the challenging antigen, where sensitization has been passive and local. Where sensitization is systemic, either passive or active, dye is administered 15 min. after challenge when given intravenously, or 15 min. (guinea pigs) or 30 min. (mice) before challenge when given intraperitoneally.

When used in this way 'Coomassie Blue' produces a readily discernible blue-mauve coloration at the sites of local anaphylactic reaction. These locally coloured areas begin to fade within 30–60 min. after appearing and within 3–6 hr. of administration the dye has completely disappeared from the animal—both systemically and from the local sites of plasma-dye extravasation.

Thus, with 'Coomassie Blue' there is no persistence of the locally coloured sites and no gradual generalized coloration of the skin, such as is the case with persisting dyes. Consequently, the same animal may be used repeatedly for investigations where a sequence of anaphylactic events is under observation.

We are applying 'Coomassie Blue' to such investigations as the rate of development of anaphylactic sensitization, the influence of a prior challenge on the anaphylactic reactivity of a sensitized site and the better visualization of both immediate and delayed local anaphylactic reactions in the same animal.

We thank Dr. G. E. Davies, of Imperial Chemical Industries, Ltd., for supplying us with the dye and for useful background information on it.

RADIOBIOLOGY

Spontaneous Agglutination and Hæmolysis in Acidified Serum of Erythrocytes from Irradiated Mice

During experiments concerning another problem, we have repeatedly observed that suspensions of washed erythrocytes from irradiated mice are unstable and agglutinate spontaneously. Since this defect in the stability of erythrocytes in suspension might be one of the causes of post-irradiation anæmia, we examined this characteristic further.

Thirty mice of strain *H* males with an average weight of 25·8 gm. were totally X-irradiated with a dose of 550 r. at the rate of 60 r./min. (180 kV., 15 m.amp., filters 1 mm. aluminium and 0·5 mm. copper, target distance 45 cm.). Blood was drawn from the tail vein into a 2 per cent sodium citrate-saline solution 24 hr. prior to irradiation and then at 2–3 day intervals. The erythrocytes were washed four times in saline solution buffered with 0·01 *M* phosphate to *p*H 7·0, which was used throughout. 0·1 ml. of 2 per cent suspension of washed erythrocytes in saline was added to 0·1 ml. of the saline solution. Each sample of erythrocytes was incubated in three test tubes for 2 hr. at 37° C. and in another three tubes for 4 hr. at 4° C. The degree of agglutination was evaluated with the naked eye in the following manner: the fine clumps of erythrocytes coating the whole hemisphere of the test-tube bottom were marked with three crosses, and the clumps coating only a small area of the bottom with a compact central button-shaped sediment with one cross. The button-shaped sediment without any coating of the test-tube bottom means that agglutination did not take place. The agglutination was, at the same time, examined microscopically. The results are expressed, on one hand, as a mean degree of agglutination (Fig. 1), and on the other hand, as a percentage of mice (from the total number of mice) with a minimum agglutination of one cross (Fig. 2).

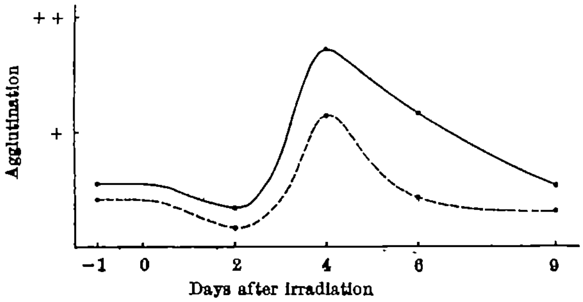

Fig. 1. Mean degree of agglutination of erythrocytes in mice prior to irradiation and at different intervals after irradiation with 550 r. (—, 37° C.; – – –, 4° C.)

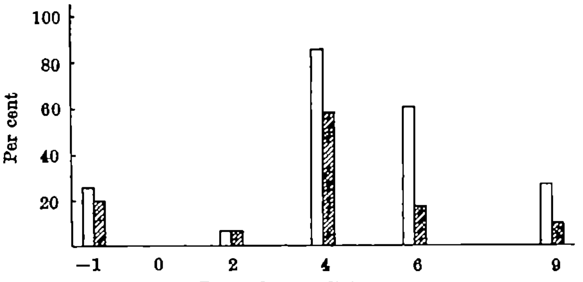

Fig. 2. Frequency of spontaneous agglutination of erythrocytes in mice prior to irradiation and at different intervals after irradiation with 550 r., expressed as a percentage of mice (from the total number of mice) with a minimum agglutination of one cross. White, 37° C.; shaded, 4° C.

The tendency of erythrocytes to agglutinate spontaneously in a saline medium reached its maximum on the fourth day after irradiation. In this series of mice, agglutination was more intense and frequent at 37° C. than at 4° C., both prior to irradiation and at all following intervals. However, in the next series of mice irradiated with 700 r., agglutination was more intense and frequent at 4° C. Hence it follows that spontaneous agglutination of erythrocytes after irradiation is not dependent on temperature within the range of 4°–37° C.

When erythrocytes from irradiated or non-irradiated mice are incubated under similar conditions in normal mouse serum, no agglutination occurs at serum dilutions lower than 1 : 1,024. Consequently, spontaneous agglutination of erythrocytes is blocked by the protein medium or by some inhibitor in the normal serum. The presence of incomplete auto-antibodies on the surface of erythrocytes was excluded by means of a direct Coombs's test. Antiglobulin serum was obtained by immunizing a rabbit with the whole mouse serum. The direct Coombs's test with erythrocytes from both irradiated and non-irradiated mice was completely negative in all cases tested.

Apart from the agglutinability of erythrocytes from irradiated mice, we have also established their marked sensitivity to the hæmolytic effect of normal mouse serum acidified with 10 per cent by volume of 0·2 *N* hydrochloric acid. Titration was performed by doubling the serum dilutions up to 1 : 16,384 using normal saline as diluent; one volume of test cells was then added and incubated for 2 hr. at room temperature (22° C.). The erythrocytes of mice irradiated with 550 r. 14 days previously became regularly hæmolysed in dilutions from 1 : 256 upwards in serum from both irradiated and non-irradiated mice. On the other hand, hæmolysis of erythrocytes from non-irradiated mice occurred sporadically in the highest serum dilutions.

From these experiments it follows that some changes occur on the surface of erythrocytes after irradiation. Consequently, these changes are the cause of their spontaneous agglutination in saline solution and of their hæmolysis in acidified normal serum. The abnormal erythrocyte surface might result in intravascular hæmolysis, the occurrence of which has been already assumed by Davis *et al.*[1] and especially by Stohlman *et al.*[2]. In my opinion, apart from the cessation of erythropoiesis and loss of erythrocytes by hæmorrhage, a significant role is to be attributed to hæmolysis of erythrocytes in the pathogenesis of post-irradiation anæmia.

I thank Dr. Z. Hill, of the District Blood Transfusion Centre at Třebíč, for the preparation of antiglobulin serum and for his valuable discussion comments.

Relative Availability of Strontium in Cereals and Milk

McCance and Widdowson[1], and later Anderson and Hoff-Jørgensen[2], have shown that the phytic acid of certain cereals may reduce the absorption of calcium from the gastrointestinal tract by the formation of insoluble calcium phytate. If strontium behaves like calcium in this respect, the absorption of strontium-90 from cereal sources in the diet may be less than that from milk which does not contain phytic acid. An experiment has been carried out to test the relative availability of strontium from wholemeal flour and milk using normal subjects from this Unit.

Three male adults (aged 38–56) took a diet of constant composition for 28–32 days. The diet (about

Table 1. Composition of Diet

	Mean consumption per day	Strontium-90 ($\mu\mu$c.)	Strontium-85 (μc.)
Milk	1,100 ml.	5·7	0·5
Bread	440 gm.	66	nil
Butter	60 ,,	0·7	,,
Jam or honey	100 ,,		,,
Bacon	60 ,,		,,
Tinned fruit, pears, pineapple, peaches	180 ,,		,,
Orange juice*	300 ,,		,,
Beer*	570 ml.		,,

* Optional extras + tea and/or coffee infusions with distilled water.

3,000 calories) is shown in Table 1. The wholemeal bread was made from grain which contained about 10 times as much strontium-90 as current British flour. It was in fact grown on soil which has been deliberately contaminated for experimental purposes. The milk was obtained from a cow which, a short time before milking, had been given an intravenous injection of strontium-85, a 65-day γ-emitting isotope of strontium. The strontium-90 was assayed on an anti-coincidence β-particle-counter and the strontium-85 on a well-type γ-scintillation-counter. The interference of the radiation from one isotope on the radioactive assay of the other was negligible. The relative absorption of strontium from the milk and flour could thus be measured by determining the ratio:

$$\left(\frac{\text{strontium-90}}{\text{strontium-85}}\right) \text{urine} \Big/ \left(\frac{\text{strontium-90}}{\text{strontium-85}}\right) \text{diet}$$

The strontium-85 activity (about 0·5 μc. per day) was derived entirely from the milk. On the other hand, the strontium-90 in the diet was not wholly derived from the special bread. The total daily intake of strontium-90 was about 70 $\mu\mu$c., some 10 per cent of which came from other components of the diet, chiefly the milk.

Table 2. Comparison of Availability of Strontium from Bread and Milk

Week	(Strontium-90/Strontium-85) urine/(Strontium-90/Strontium-85) diet J. F. L.	G. E. H.	T. E. F. C.
1	0·88	0·98	0·74
2	0·75	1·20	0·69
3	0·83	0·95	0·72
4	1·26	1·10	0·75
5	0·84	1·10	0·68
Mean	0·91	1·06	0·71

Overall mean and standard error 0·90 ± 0·05.

The results are shown in Table 2. Urine was bulked over seven-day periods. During the first four weeks the diet was as in Table 1. During the fifth week the diet was of the same composition except that the milk contained no strontium-85 and the bread much less strontium-90 since it was baked from a commercial British flour of the same calcium content as the more active grain.

It will be seen that the mean ratio of:

$$\left(\frac{\text{strontium-90}}{\text{strontium-85}}\right) \text{urine} \Big/ \left(\frac{\text{strontium-90}}{\text{strontium-85}}\right) \text{diet}$$

ranged from 0·71 to 1·06 for the different subjects while the overall mean and standard error is 0·90 ± 0·05. Even although about 10 per cent of the strontium-90 in the diet came from non-cereal components, it may be concluded that the strontium in wheat and milk in human diet is approximately equally available.

We thank the Director and staff of the Radiobiological Laboratory, Agricultural Research Council, Wantage, for the supply of the grain used in this experiment and the Director and staff of the Field Station, Agricultural Research Council, Compton, for the supply of the radioactive milk.

BIOLOGY

A Late-Glacial and Post-Glacial Climatic Correlation between East Africa and Europe

The classical work on the Quaternary chronology in Africa has been carried out in East Africa by geologists, palæontologists and archæologists. The general scheme of a sequence of pluvial and non-pluvial periods which had been developed was later on widely adopted in all parts of Africa. Revaluation of the factual evidence and warning against uncritical acceptance of the East African pluvial chronology, especially from geological quarters[1–3], led to the conclusion that there existed in East Africa evidence for at least one major pluvial, the Upper-Pleistocene Gamblian pluvial.

Botanical evidence has so far not been forthcoming from the East African area, but some palynologists are at present engaged in the analyses of a number of pollen containing cores from Ruanda-Urundi, Uganda, Kenya and south Tanganyika. I am carrying out my work mainly in the last two areas and have made several borings in Lake Naivasha, Lake Narasha, and in swamps and tarns on the Cherangani Hills and Mount Kenya. The preliminary results of a boring at Kaisungor in the Cherangani Hills open a new perspective for the study of the climatic chronology in East Africa and are described shortly. A more detailed description will be published at a later stage[4].

The Cherangani Hills form part of the western rim of the Rift Valley in north-west Kenya. The boring was made in a swamp at Kaisungor situated in a valley head at ± 1° N. lat. and 35° 28′ E. long. at 9,600 ft. (292 m.) altitude.

The highest point in the Kaisungor area is 10,000 ft. (3,048 m.). The part around the swamp is at present covered by montane conifer forest. The tree line in the Cherangani Mountains is found at 10,500 ft. (3,200 m.). Under natural conditions the summits would probably be covered by bamboo forest mixed with trees of the highest forest. Under undisturbed conditions a zone of high shrubs of *Stoebe kilimandscharica* occurs just above the forest on several of the East African mountains. Tall Compositae shrubs are often found in great numbers in the lower part of the ericaceous belt above the forest. On the eastern mountains in East Africa the ericaceous belt usually occurs between 9,842 ft. (3,000 m.) and 11,811 ft. (3,600 m.), but sometimes goes up as far as 13,123 ft. (4,000 m.) (ref. 5). The lowest level of this belt in the Cherangani Mountains is the tree line at 10,500 ft. (3,200 m.). The highest vegetation belt or Alpine

Table 1. TENTATIVE COMPARISON OF LATE- AND POST-GLACIAL CHRONOLOGY OF EAST AFRICA AND EUROPE

Age calculated according to sedimentation (B.C.)	Zones (see van der Hammen and Gonzalez, refs. 6 and 7)	Vegetation at Kaisungor	Climate at Kaisungor 2,926 m. altitude	Europe
700	VIII	Tree-line coming down	Wet, becoming colder	Subatlanticum
3,010	VII	Forest maxima	Warmer Colder	Subboreal
5,790	VI	Forest closed Tree-line rising	Warmer and wet Temperature rising	Atlanticum
6,675	V	Tree-line around the swamp	Warmer and relatively wetter	Boreal
8,040	IV	Open vegetation. Stoebe maximum Tree-line below swamp	More humid rising temperature	Preboreal
8,840	III	Tree-line low, grass maximum	Cold and dry	Younger Dryas time
	II	Compositae maximum	Warmer and dry	Allerød
	I	?	?	Older Dryas time
		?	?	Bølling
(*GRN* 8,048) 10,690 ± 100		Maxima of grasses and ericaceous belt	Cold and dry	Oldest Dryas time
		Alpine vegetation	Very cold and dry	

belt, which is often rich in tussock-grassland, does not occur in the Kaisungor.

At the site of the boring the swamp was 3·70 m. deep. The following pollen types have been included in the pollen sum: the forest trees, *Stoebe*, Compositae (which may include some swamp plants), the shrubs of the ericaceous belt (*Protea*, *Myrsine*, *Alchemilla*, etc.) and Gramineae.

As in the case of the Eastern Cordillera of Colombia (van der Hammen and Gonzalez[6,7]) a high percentage of Gramineae can be taken as an indication of a lower temperature. The grass pollen is principally produced by the open tussock-grassland of the ericaceous and Alpine belts.

The general trend of the pollen diagram can be interpreted as follows. The high percentage of grass pollen at the bottom of the diagram and the maximum of other plants of the ericaceous and Alpine belts above that indicate cold conditions as could occur at an altitude of at least 3,400 m. The maximum of Compositae between −2·70 and 2·45 m. indicate the approach of the tree line.

Another cold period between −2·45 and 2·30 m. is suggested by a grass pollen maximum. The forest types then show a definite rise which is in the beginning marked by a maximum of Stoebe. Optimal conditions of temperature and rainfall for the conifer forest of the higher altitudes seem to have existed between −1·70 and 1·15 m. Above −1·15 m. the forest gradually opens up. The climate apparently becomes less favourable.

The age of a sample from level −2·85–3·00 m., as measured at the Radiocarbon Station, Groningen, was found to be 12,650 ± 100 B.P. (*GRN* 3,048) (10,690 ± 100 B.C.): the Suess effect was taken into account in this determination. More radiocarbon dates will be obtained later. A provisional absolute time-scale has been worked out on the assumption that the annual growth of the peat deposits was approximately the same throughout the profile, namely, 0·231 mm. per annum. It then appears that the changes in temperature which occurred are in general contemporaneous with the climatic chronology of the Late- and Post-Glacial of Europe (Table 1).

The dated horizon (−2·85–3·00 m.) falls in the Oldest Dryas time of Europe and represents also a cold period in the Cherangani Mountains.

The Allerõd is well represented between the levels −2·49 and 2·72 m. (according to sedimentation 8,840–9,840 B.C.).

A more detailed analysis supported by more radiocarbon dates will be necessary to prove whether there existed an equivalent to the Bõlling Interstadial in East Africa.

In general Table 1 resembles the results obtained by van der Hammen and Gonzalez in the Andean mountains of Colombia and suggests very strongly that the climatic chronology of the Late- and Post-Glacial of Europe also applies to equatorial East Africa.

Conservatively estimated the tree line, during the Oldest Dryas time, was 500–600 m. lower than at present, which accounts for a drop in temperature of at least 3°–4° C. During the coldest phase of the Weichsel Glacial the temperature would have been

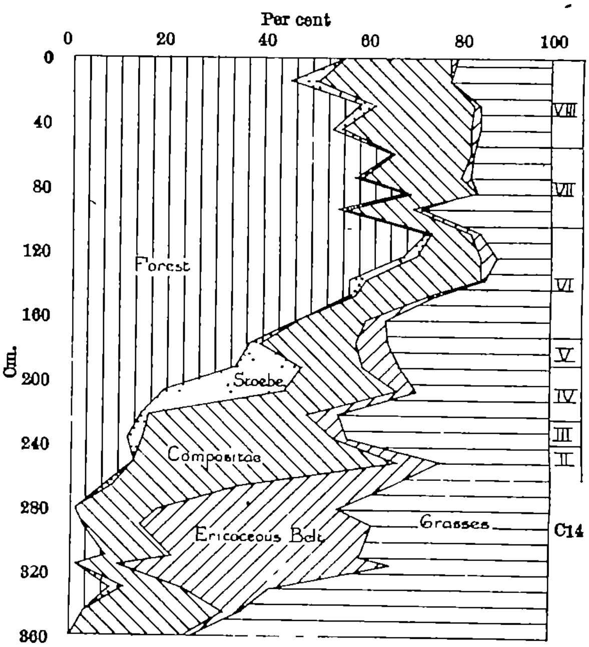

Fig. 1. Pollen diagram of Kaisungor. The Roman figures indicate the periods described by van der Hammen and Gonzalez (refs. 6 and 7)

appreciably lower. These changes in temperature occurred apparently on a world-wide scale (Flint and Brandtner[8], Emiliani[9,10], van der Hammen and Gonzalez[6,7]) and were contemporaneous. The implications on humidity, geological events, the life of man, animals and plants, etc., will have to be studied in great detail in order to obtain a better understanding of the Quaternary in Africa and of its so-called Pluvial periods.

I thank the South African Council for Scientific and Industrial Research for its continuous support of this research, and Prof. H. de Waard, of the Radiocarbon Station, at Groningen, for having the sample *GRN* 3048 dated.

A Specific Stimulatory Action of Indolyl-3-Acetic Acid on Potassium Uptake by Plant Cells, with Concomitant Inhibition of Ammonium Uptake

THE evidence collected so far for an effect of growth-promoting concentrations of auxins on cation uptake by plant cells gives a somewhat confused picture. Auxins have been variously reported as promotive, inhibitory, or without effect, according to the conditions of the investigation[1-4]. I wish to report here experiments yielding clear evidence for a marked effect of indolyl-3-acetic acid (IAA) on potassium and ammonium uptake by segments of sunflower hypocotyl. In the case of potassium the effect is stimulatory, in that of ammonium, inhibitory.

Table 1. EFFECT OF 10^{-4} *M* INDOLYL-3-ACETIC ACID ON THE UPTAKE OF AMMONIUM AND POTASSIUM IONS BY SEGMENTS OF SUNFLOWER HYPOCOTYL

Treatment	Water uptake (percentage initial fresh weight)		Cation uptake (μequiv./gm. initial fresh weight) K^+		Cation uptake (μequiv./gm. initial fresh weight) NH_4^+

	9·4		3 6		13 1	
	9·3		4 5		14·6	
+ IAA	48 7	47 2	14·2	14·3	10 6	10·5
	46·4		14·2		10·5	
	46 5		14·5		10·3	

35 segments (approximately 1 gm.) in 5 ml. medium buffered at $pH = 6·5$ with K_2HPO_4, KH_2PO_4, $(NH_4)_2HPO_4$ and $NH_4H_2PO_4$. Final concentrations: NH_4^+ and K^+ each $6 3 \times 10^{-3}$ *M*; phosphate 10^{-2} *M*. Uptake measured after 15·5 hr.

The experiments were carried out with etiolated, 5–9-day-old seedlings of *Helianthus annuus* var. Jupiter. 1-cm. segments were removed at a distance of 1 cm. below the crook and were washed for 6–8 hr. in running water, then rinsed in distilled water, blotted, weighed and transferred to Petri dishes containing 3–5 ml. solution buffered with phosphate. The cations under investigation were added to the solution as indicated in Tables 1, 2 and 3. Uptake was determined by analysis of the external solution, by flame photometry in the case of potassium, sodium and lithium, and by the Conway method in the case of ammonium. The IAA concentration used was such as to produce maximum stimulation of water uptake.

Table 1 gives details of a typical experiment where the uptake of K^+ and NH_4^+ was measured simultaneously. It will be seen that IAA brought about a large increase in K^+ uptake, while NH_4^+ uptake was depressed. Both effects were significant at the $P = 0·01$ level.

In order to ascertain whether the stimulatory effect was specific for potassium, or whether the uptake of other monovalent cations was similarly affected, further experiments were carried out comparing potassium uptake with that of sodium and lithium. The results of three such experiments, each performed in duplicate, are given in Table 2. The figures in Table 2 are for net uptake, as it may be assumed that, simultaneously with uptake, loss of cations from the tissue into the solution took place. It will be noted that in several cases loss was greater than uptake. Table 2 shows that the difference between control and IAA treatment was considerably bigger in the case of potassium than in that of lithium or sodium. An analysis of variance made on the three experiments treated together indicated that the stimulation of K^+ uptake was significant at the $P = 0·001$ level, the effect on Li^+ at $P = 0·01$, while the effect on Na^+ uptake was not significant even at $P = 0·2$.

Reinhold[6] observed a release of ammonium ions by IAA-treated tissue, an effect probably closely related to the inhibition of ammonium uptake reported here. She also mentioned, without quantitative data, a reduction in the loss of potassium to the solution in the presence of IAA. The influence of IAA on cation efflux into a solution initially free of the cation under consideration was therefore investigated. No significant effect of IAA on the loss of sodium could be detected. The previously reported

stimulation of ammonium release was confirmed. Table 3 gives results of a typical experiment in which the release of potassium was measured. The influence of IAA in diminishing potassium loss was significant at the $P = 0·001$ level.

In the present investigation, therefore, IAA had no significant effect on the passage of sodium either into or out of the cell; it had an inhibitory influence on the entry of ammonium and a stimulatory effect on its release, while the auxin had the opposite effect on the movement of potassium, that is, a stimulation of uptake and a reduction in release. The results thus reveal a relatively high degree of specificity in the action of IAA on cation movement. A hint of similar differential effects may perhaps also be seen in the results of Pickles and Sutcliffe[7], who noted a reduction in K^+ efflux from IAA treated beet disks under conditions where Na^+ uptake was depressed.

Effects of Indolyl-3-Acetic Acid on the Movement of Nutrients within Plants

IT has been suggested that apical dominance and the 'correlative inhibition' of lateral buds may involve the diversion of nutrients towards actively growing regions, and that the role of auxin in correlative inhibition may be to stimulate the movement of nutrients towards meristematic regions[1], which are known to be centres of high auxin production. Investigations of the movement of metabolites within the plant using isotopically 'labelled' compounds have, indeed, frequently indicated that such substances tend to move out of mature leaves towards actively growing regions such as young developing leaves and fruits[2,3]; but no attempt has apparently been made to determine whether such movement is affected by the auxin content of the developing organs.

Radioactive compounds afford a ready means of investigating this problem and preliminary experiments with this object were carried out by two of us (A. B., J. M.) in the University of Manchester several years ago[4,5]. In one of these experiments, young plants of *Solanum andigena* were divided into three series (each of 10 plants) as follows: (1) untreated, intact plants; (2) plants decapitated in the first fully extended internode and the cut surface covered with lanolin; (3) plants decapitated and the cut surface covered with lanolin containing 200 p.p.m. indolyl-3-acetic acid. A drop of aqueous solution containing 0·2μ of 2 per cent ^{14}C-sucrose was applied to the upper surface of the 3rd or 4th mature leaf of each plant. After 6 hr. the plants were cut up to separate the apical region of the shoot of the intact plants, and the stumps of the uppermost internodes of the decapitated plants of series (2) and (3). These tissues were then dried and powdered. Solid samples (of equal weights) were prepared from the powdered material and placed on planchettes 2 cm.^{2} in area. These were counted at a distance of 2 cm. from the end-wall of a Geiger–Muller tube. The results are given in Table 1.

Table 1. EFFECT OF DECAPITATION, WITH AND WITHOUT APPLIED INDOLYL-3-ACETIC ACID, ON ACCUMULATION OF CARBON-14 IN THE TOP INTERNODE OF PLANTS OF *Solanum andigena*

Treatment	Activity (counts/min.) with *S.D.* *
(1) Intact plant	45·0 ± 2·6
(2) Decapitated plus lanolin	33·7 ± 2·3
(3) Decapitated plus IAA in lanolin	61·8 ± 2·9

* Standard deviation calculated according to Comar (ref. 6). (In this experiment, the parts from the 10 plants of each treatment were combined.)

It is seen that very much less radioactivity occurred in the stumps of the decapitated plants supplied only with lanolin than in the intact plants. When, however, indolyl-3-acetic acid was applied to the stumps after decapitation, the accumulation of radioactivity was greatly increased, although the period of the experiment extended over only 6 hr. These results were confirmed by other experiments involving autoradiography of whole plants. Similar results were obtained by Moorby[5] with phosphorus-32 applied to Meteor pea, using both autoradiography and direct counting of activity.

A further series of experiments has now been carried out by one of us (C. R. D.) which fully confirms the earlier experiments. Plants of Meteor pea bearing 4–5 expanded leaves were selected for uniformity and divided into three series, each of 10 plants. Two series of plants were decapitated, and 12 hr. after decapitation the cut stumps were covered with either (*a*) lanolin alone or (*b*) lanolin containing 1,000 p.p.m. indolyl-3-acetic acid. After 3 hr. a solution containing 1·0 μc./0·05 ml. of ^{14}C-sucrose was applied to one of the mature leaves of each of the decapitated plants and of the third series of intact plants. After a further 8 hr., the decapitated stumps and the corresponding internodes of the intact plants were removed, weighed and pulverized in liquid air. The tissue samples were extracted with 80 per cent aqueous methanol, and the filtered extracts were reduced to a small volume and spread evenly over the surface of planchettes. After drying, the radioactivity was counted with a proportional counter converter in association with a 'Panax' scaling unit. The activities are shown in Table 2, expressed as counts/min./100 mgm. fresh weight of tissue, after correction for 'background'.

Table 2. ACCUMULATION OF METHANOL-SOLUBLE CARBON-14 IN TOP INTERNODES OF INDOLYL-3-ACETIC ACID TREATED AND DECAPITATED PLANTS OF *Pisum sativum* VAR. METEOR

Treatment	Mean activity (c.p.m.) of 10 internode samples ± *S.E.* of mean
Intact plant	129·4 ± 27·7
Decapitated plus lanolin	47·7 ± 10·4
Decapitated plus IAA (1,000 p.p.m.) in lanolin	116·6 ± 25·7

In this experiment the samples from each plant were counted separately.

It is seen that the application of indolyl-3-acetic acid to the decapitated stump has resulted in a significantly greater accumulation of radioactivity than in the plants to which only lanolin was applied.

The foregoing results seem clearly to indicate that externally applied indolyl-3-acetic acid in some way stimulates the movement of substances towards the point of application. This conclusion is supported by the results of a variety of experiments involving Scots pine, birch and pea seedlings, in which autoradiography was mainly used[5]. Moreover, it was found that ^{14}C-sucrose moves not only into decapitated internodes, but also into mature leaves to which auxin has been applied externally.

It is possible that the effect of indolyl-3-acetic acid on the transport of substances within the plant is an indirect one, resulting from the stimulation of growth in the tissues to which it is applied; it is well known that nutrients tend to move towards actively growing regions in the normal plant, possibly because synthetic processes are proceeding actively in such regions, which thus constitute metabolic 'sinks'. It is also known that high concentrations of exogenously applied indolyl-3-acetic acid will stimulate the renewal of growth in differentiated tissues, such as the decapitated internodes used in the present experiments. The renewal of growth in differentiated tissue is not immediate, however, and it seems very unlikely that over the short period of the experiments (6–11 hr.) any appreciable growth had yet commenced, especially in the experiments in which indolyl-3-acetic acid was applied to fully mature leaves. Moreover, in further experiments (not described here), autoradiographs of extracts of the stumps of decapitated plants treated with indolyl-3-acetic acid, partitioned by paper chromatography, indicated that no new labelled compounds were present as compared with those found in the leaf to which the ^{14}C-sucrose was applied. Thus, it would seem that the effect of indolyl-3-acetic acid on transport of metabolites is not primarily to create a metabolic 'sink' by stimulating synthesis, but may be rather to stimulate active uptake and accumulation by the tissues to which it is applied. Zimmermann[3] has argued that the exchange of sugars between phloem and surrounding tissues may be analogous to the active secretion of sugars by nectaries, which is known to be stimulated by auxin[7].

This effect of auxin on the movement of substances within the plant is paralleled by the effect of kinetin on the movement and accumulation of amino-acids, sugars and inorganic ions when applied to differentiated leaf tissue, as observed by Mothes and his co-workers[8,9]. In the experiments with these latter substances and with kinetin, however, observations were made on movement within a single leaf, whereas in the present experiments with indolyl-3-acetic acid phloem transport over considerable distances was evidently involved. It would seem that auxin-directed transport may be important in the re-distribution of nutrient reserves from storage organs and older tissues to young growing regions, and may also play a part in apical dominance and the correlative inhibition of buds. It is possible that the phenomena reported here are also related to the effects of auxins on leaf-senescence, reported by Osborne[10].

Role of the Shikimic Acid Pathway in the Formation of Tryptophan in Higher Plants: Evidence for an Alternative Pathway in the Bean

IT has been assumed generally, without adequate supporting evidence, that tryptophan and other indole compounds are generated via the shikimic acid pathway in higher plants. Evidence for this biosynthetic pathway has been derived mainly from microbial studies and from theories based on the unity of biochemistry[1-3]. Proof that shikimic acid is a precursor to the aromatic amino-acids, phenylalanine and tyrosine, has been clearly obtained by McCalla and Neish[4]. It has also been demonstrated that higher plants possess a mechanism to convert quinic acid to shikimic acid and phenylalanine and tyrosine[5-7]. The latter aromatic acids are assumed to be derived from prephenic acid, which is transformed to phenylpyruvic and *p*-hydroxyphenylpyruvic acids, and afterwards to phenylalanine and tyrosine, respectively[1]. Since anthranilic acid, a precursor to tryptophan, may be derived from a separate branch of the aromatic pathway in micro-organisms[8], one might expect a similar situation to exist in higher plants as well. Recently, Wightman *et al.*[9] have indeed reported that shikimate-U-^{14}C gives rise to tryptophan and gramine in young barley seedlings in the light. Similar investigations on the conversion of quinate-U-^{14}C and shikimate-U-^{14}C to tryptophan in bean seedlings in the light and dark have been under investigation in this laboratory.

Young trifoliate leaves of the bean (*Phaseolus vulgaris* L.) plants were supplied through cut petioles with 6 mgm. of shikimate- or quinate-U-^{14}C (specific activity approximately 35,000 c.p.m. per μmole) in 5 ml. of 0·01 *M* phosphate buffer, *p*H 6·75. After absorption of the labelled compounds and small aliquots of water, the leaves were placed in water in small chambers in the dark or under fluorescent lights. The leaves receiving light were supplied with about

250 foot-candles (2,690 lux). Air free of carbon dioxide was continuously passed through the chambers and carbon dioxide evolved from the tissues was trapped in alkali. The leaves were gathered after 24 hr. and extracted.

Quinate and shikimate were separated from the tissue extracts by gradient elution with acetic acid from 'Dowex 1-X8' (acetate-form)[4]. Bound amino-acids were liberated by hydrolysis with barium hydroxide[10], and both free and bound amino-acids were separated by column chromatography[11]. Tryptophan was identified by paper chromatography and by a modified Salkowski reaction as follows: to 50 ml. of 35 per cent perchloric acid, 1 ml. of 0·367 ferric chloride was added. Two ml. of sample in citrate buffer, *p*H 5·28 (ref. 11), was combined with 4 ml. of reagent. The reaction mixture was heated for 15 min. in a water bath at 70° C. and then cooled to room temperature. The absorbancy of the yellow colour, which was stable for more than 96 hr., was determined in a spectrophotometer at 455 mμ.

Tyrosine and phenylalanine were identified by their elution pattern from the column, followed by paper chromatography and autoradiography. Identification of quinate and shikimate involved elution patterns from columns, paper chromatography, autoradiography, and reactions on chromatograms with potassium periodate–piperazine–nitroprusside[12] and the thiobarbituric acid reagent of Saslaw and Waravdekar[13].

Table 1. CONVERSION OF QUINATE-U-^{14}C TO SHIKIMATE-U-^{14}C, THEIR CONVERSION TO AROMATIC AMINO-ACIDS, AND $^{14}CO_2$ EVOLVED IN BEAN LEAVES

Treatment, bean leaves	C.p.m./μmole				$^{14}CO_2$ evolved as percentage of total carbon-14 supplied
	Shikimate	Quinate	Phenylalanine + tyrosine *	Tryptophan *	
Shikimate-light	18,560	0	4,620	16	1·7
Quinate-light	17,240	22,170	2,880	10	1·1
Shikimate-dark	21,910	0	4,175	8	5·6
Quinate-dark	32,510	20,850	1,785	3	6·9

* Free and bound.

Table 1 shows results from a typical experiment. Similar experiments with quinate-U-^{14}C were carried out at three other times.

Little carbon-14 was incorporated into free or bound tryptophan, although there was a slightly greater incorporation in the light than in the dark. Phenylalanine and tyrosine, however, were preferentially labelled when either quinate- or shikimate-U-^{14}C was supplied in the light or dark. Shikimate was a more efficient precursor than quinate. There was no evidence of conversion of shikimate to quinate in the light or dark. Quinate, on the other hand, was readily converted to shikimate, as has been shown previously[5–7].

Although based on information of a negative nature, it seems very unlikely that the shikimate pathway is responsible for tryptophan synthesis in the bean. It is, of course, possible that the pathway to tryptophan in the bean constitutes an exception to the expected pathway.

Since more radioactivity was found in tryptophan in the light than in the dark, it is possible that this resulted from photosynthetic fixation of respiratory $^{14}CO_2$ into other compounds, such as serine, which leads to the tryptophan side-chain. Experiments carried out under light intensities higher than that reported here might result in greater adventitious labelling of tryptophan in this manner. Table 1 shows that dark-treated tissues liberated about 5 times more $^{14}CO_2$ than did light-treated tissues. The difference may have been due to photosynthetic fixation of evolved $^{14}CO_2$.

The irreversibility of the quinate→shikimate conversion leads one to suggest that this pathway in bean may not be directed through the intermediate compounds 5-dehydroquinate and 5-dehydroshikimate.

Premature Bursting of Sultana Buds

OF the two buds formed in the axil of vine leaves in spring, one usually develops into a lateral shoot; the other (hereafter termed 'bud') becomes dormant, and does not burst until the following spring.

Huglin[1], working with varieties of wine grapes, found that up to three terminal buds could be induced to burst without first undergoing winter dormancy. Bud-burst was induced by simultaneous removal of lateral shoots and growing points, provided that the leaves subtending the buds were not more than six weeks old.

Bernstein and Klein[2] reported that, in parts of Palestine, shoots of the variety Chasselas Doré, pruned to eight buds after the normal harvest, could produce a second crop following bud-burst in the terminal positions. These buds are up to six months old at the time of bursting.

This communication reports bud-burst without winter rest in sultana vines having growing points still intact. The vines were grown in aerated solution culture at this Station, during the summers of 1959 and 1960.

During the 1959–60 season, laterals on young sultana rootlings in solution culture were pinched out as they appeared (October to end of December) to confine growth to single shoots. Nutrient solutions were completely replaced on December 8, and monthly thereafter. The experiment ended in February. Vines made good growth and by late December shoot-lengths ranged from 100 to 200 cm., and nodes numbered 30–40. Bud-burst commenced on December 22 and continued during January and February. Fig. 1 illustrates a typical premature bud-burst

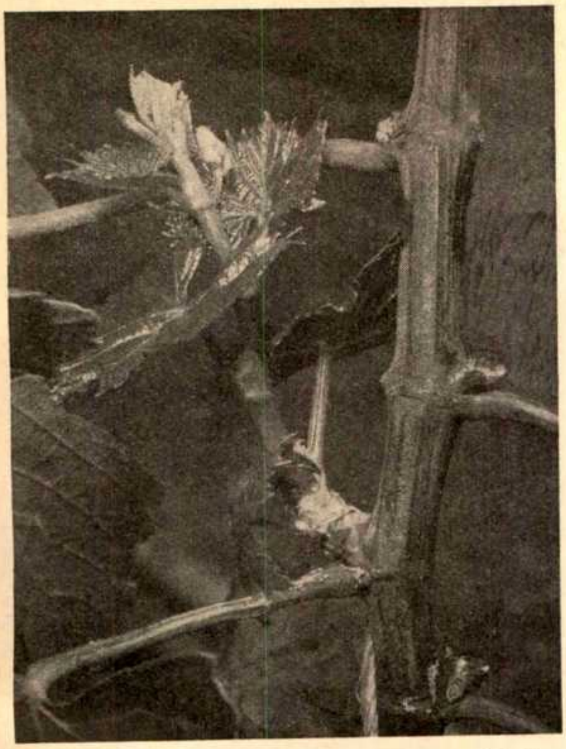

Fig. 1. Premature bursting of sultana bud; note scars left after removal of laterals

By February, at least one of the basal 25 buds had burst on 55 of the 72 vines; on 16 vines, more than three buds had burst. Of 164 buds which burst, 46 were on the basal third of the shoots. The number of buds bursting prematurely ranged up to 12 per vine.

In another experiment, two young sultana rootlings with immature shoots were transferred from solid media to solution culture in January. The shoots were cut back to 12 buds (1/3 of shoot-length) and all laterals removed but primary leaves were left intact. At the time of transfer basal leaves were 16 weeks, and leaves at node 12 were 12 weeks old. After 12 days in solution culture, 11 buds on one vine and 6 on the other had burst. Buds burst basipetally.

To examine the abnormal bud-burst occurring in solution culture, five treatments (varying numbers of both young leaves and untipped lateral shoots) were applied to young sultana rootlings (11–15 nodes) in October 1960. Contrary to the previous season, nutrient solutions were not changed but nutrients were added from time to time to maintain active growth. Treatment details and data on buds bursting by December 30 are given in Table 1.

Table 1. TREATMENTS APPLIED TO LATERAL SHOOTS, AND PREMATURE BUD-BURST IN SULTANA VINES GROWN IN SOLUTION CULTURE AS AT DECEMBER 30

Treatment of laterals	No. of buds bursting prematurely	No. of vines affected	Mean No. of primary nodes per vine
1 Removed on appearance	12	5	41
2 Removed when 4 nodes long	1	1	38
3 Tipped when 4 nodes long*	0	0	37
4 Tipped when 8 nodes long*	0	0	36
5 Removed progressively when distal two were 4 nodes long	1	1	30

* Further lateral growths were removed on appearance

Of the 14 buds which burst, 4 (3 from one vine of treatment 1, and 1 from treatment 5) were associated with loss of the shoot tip due to wind. A further 3 cases (from two vines of treatment 1) were associated with wind damage to the shoot tip without loss of the growing point; damage occurred within 10–20 days of the first appearance of the leaf subtending the bud which burst. These 7 buds were in the terminal region of the shoot at the time of damage, and burst 2–3 weeks later.

In 4 other cases (from two vines of treatment 1) the subtending leaf was at least 10 weeks old at the time of bud-burst. These buds were in the basal portion of the shoot, and there was no damage to shoot tips. In all cases of premature bursting, affected vines had active growing points on either the main shoot or lateral extension at the time of burst.

No bud-burst occurred on 7 of the 18 vines in treatments 2, 3 and 4 although growing points on main shoots were lost; after short periods these were replaced by laterals.

These observations are in accordance with Huglin's hypothesis—of the production of bud-burst inhibitor in growing points and young leaves. But in our experience, buds older than 6 weeks, which he found dormant, burst on numerous occasions. Contrary to the findings of both Huglin[1] and Bernstein and Klein[2], bud-burst was not confined to the terminal positions. This suggests that the onset of dormancy is delayed in solution culture, or that leaching of roots can interfere with bud-burst inhibition. Evidence suggests that even a temporary depression (7 days) of terminal growth retards the development of this inhibitor.

Gradient Analysis in Swamp Forests

DURING 1960 and 1961 we studied periodically flooded wetlands dominated by the trees *Larix laricina*, *Thuja occidentalis*, and *Ulmus americana* along transects from lake margins to the upland in the Rideau Lakes Region of Ontario. This vegetation shows distinct belts of the dominants from the air which have often been described as separate plant communities and were interpreted as stages in a hydrosere[1,2].

Relative elevations along transects were determined with a hand level and stations measured at 50-m. intervals. At each station we measured the water-level repeatedly, determined *p*H and Eh in the field for a hummock and a hollow both at 5 and 30 cm. depth, and collected the four corresponding soil samples. By spinning a cross we determined four directions. The closest ¼ sq.m. of hummock in each direction was sampled for herb- and ground-layer. The procedure was repeated for the hollows. In a 10 × 10 m. quadrat density and basal area in the tree layer and density and cover in the shrub layer

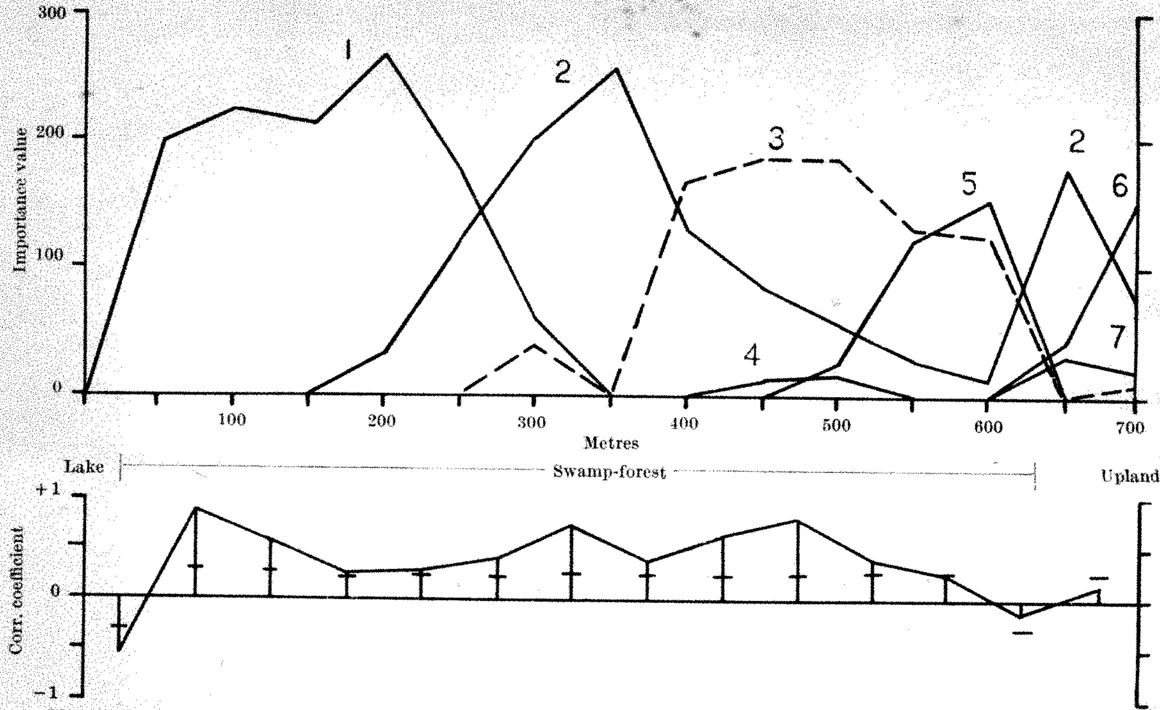

Fig. 1. Transect of a swamp forest near Portland, Ontario. Above, Importance values for the sampled stations of (1) *Larix laricina*, (2) *Thuja occidentalis*, (3) *Ulmus americana*, (4) *Fraxinus nigra*, (5) *Acer saccharinum*, (6) *Acer saccharum*, (7) *Fraxinus americana*. Below, correlation coefficients of the vegetation between adjoining stations. Probability at the $P = 0{\cdot}05$ level is indicated by –

were noted. From six points, selected close to randomness within 10 m. radius of each station, we sampled trees using the quarter method[3]. The limits of the quadrants were again found by spinning a cross.

The analysis of the gradient may be shown on one transect. About 30 species were noted per station. The whole transect yielded a total of 161 species of tracheophytes, bryophytes and ground-lichens. Sampling at a station comprises less than the commonly used minimum areas; but an increase of the sampled area rectilinear to the transect raised the species number only slightly and demanded a much longer sampling time. Due to micro-environmental differences a larger sampling area mixes also elements narrowly restricted to sections of the gradient and would give a false picture of higher continuity and homogeneity.

When the importance values[4] of the trees are plotted for each station, as at the top of Fig. 1, a gradual replacement of one species by another is seen. Only at the upland margin do the values change rapidly. Combined frequency and cover values for plants in the lower layers give very similar patterns. However, these do not coincide with the ranges of the dominant trees and show a wide variety of width and position of the ranges. Most patterns resemble normal curves. A large number of curves is difficult to assess by inspection alone. Trends of ranges to coincide and coinciding modalities of curves may be hidden. These trends could give indications of limits of communities or seral stages. Therefore we calculated various community coefficients[5] and Pearson's r for the changes between adjoining stations. For the transect shown we calculated r also for every station with each other station.

The degree of correlation depends on the way the data are adjusted, which is a matter of choice. We tried to simplify the procedure of tabulating. Further, we wanted to avoid high correlations resulting from excessive loading through the truism that rare and small plants are so throughout and that the number of species in the top two layers is always lower than in the two other layers. We hope to improve adjustments with the aid of a computer. For the tree layer we used importance values divided by three. Cover percentages were listed for the shrub layer. The added cover percentages of the eight quadrats were divided by two for the herb layer. The same was done for the ground layer. Seedlings and saplings were counted as separate items in their respective layers. The layers are thus counted in the ratio 1 : 1 : 4 : 4 and the values on one station could add up theoretically to 1,000. The number of items occurring in the station pairs compared is taken as n, which fluctuates from 39 to 63.

The r-values of adjoining stations are shown in the figure with a transverse bar for a probability of significance of $P = 0{\cdot}05$ derived from the t-test. All neighbouring stations within the swamp forest except the last pair are significantly correlated. Contrarily, the lake shore and the upland limit appear as sharp breaks. If the distance of the two stations compared is increased linearly, r drops geometrically, decelerating into significant negative correlations. Other comparisons based either on cover or only on species shared and not shared between stations give similar patterns. The sign test[6] proved very useful for the latter comparison as it permitted also an assessment of probability. Slight fluctuations of the lines connecting values of similarity for adjoining stations are not paralleled by the various methods. Different adjustment of the data varies the fluctuations as well.

The connecting line of the r-values permits an assessment of the steepness of the vegetation gradient for the distance of the compared stations. A dip over short distances into negative correlations indicates an ecotone. Peaks and plateaux of significant positive correlation show high homogeneity. The mean level of this line changes with varying sampling intensity at a station and with the distances between stations. Standardized sampling allows comparison of the steepness of the vegetation gradient in different localities and correlation of the changes of environmental factors with the overall changes of the vegetation.

We did not find a sufficiently sharp break along the transects within the swamp forests to warrant a separation into different communities despite the extreme dissimilarity of the vegetation several stations apart.

A Possible Link between Root Initiation and Anthocyanin Formation

IN an examination of the rooting of cuttings from *Acer rubrum* L. and *Eucalyptus camaldulensis* Dehn. seedlings the unexpected observation was made that the rooting response of *Acer rubrum* cuttings appeared to be related more closely to the amount of anthocyanin formed in the leaves during the experimental period than to the treatments under investigation.

Acer rubrum and *Eucalyptus camaldulensis* seedlings were grown in controlled environment rooms at 23° C. Cuttings were made from 4–5-week old *Acer* seedlings by cutting the seedlings immediately above the cotyledons. 10-cm. tip cuttings were taken from *Eucalyptus* seedlings about 13 weeks old. Rooting of the cuttings was tested in continuous light at 26° C. The bases of the cuttings were immersed in a darkened rooting solution of 1·0 mgm./l. indolyl butyric acid (IBA), an auxin and concentration previously determined to be optimal.

The cuttings were used in investigations of some of the physiological factors affecting root formation. Though some of the treatments tested yielded significant overall effects there was considerable variation in the number of roots formed on replicate cuttings within any one treatment. In the *Acer rubrum* cuttings this variation in number of roots formed appeared to be correlated with the redness of the leaves on the cutting. The red coloration developed during the experimental period, very little or no redness being present in the leaves at the start of the experiments. A typical relation between mean roots/cutting and leaf colour found in a preliminary experiment is shown in Fig. 1. Another experiment then was examined quantitatively. The anthocyanin present in the two leaves retained on each cutting was extracted by treatment with cold 0·1 *N* hydrochloric acid for 24 hr. The amount of anthocyanin present in the leaves was estimated, spectrophotometrically, by measuring the absorption of the extract at 510 mμ. A highly significant correlation ($r = 0{\cdot}677$, $P < 0{\cdot}01$) was observed between the total amount of anthocyanin present in the leaves of each cutting and the number of roots formed on those cuttings (Fig. 2). The correlation between anthocyanin concentration (anthocyanin units/gm. fresh weight of leaves) and number of roots was also highly significant ($r = 0{\cdot}608$, $P < 0{\cdot}01$).

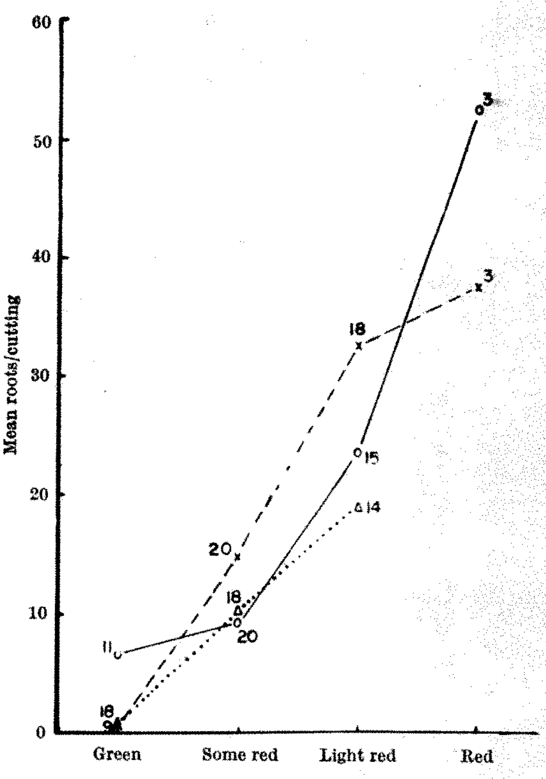

Fig. 1. Relation between leaf colour and mean roots/cutting of *Acer rubrum*, three weeks after treatment with indolyl butyric acid. Cutting from seedlings grown under: ○, continuous light; ×, 16-hr. light period; Δ, 8-hr. light period. Numbers indicate number of plants averaged for each experimental point

No correlation between anthocyanin content of the leaves and root formation was observed in cuttings rooted in distilled water alone. No difference could be detected between the total amount of anthocyanin in the leaves of cuttings rooted in distilled water and in the leaves of the cuttings rooted in 1·0 mgm./l. IBA. This suggests that anthocyanin formation in the leaves of the cuttings was not dependent on the number of roots formed. In terms of concentration of anthocyanin (anthocyanin units/gm. fresh weight of leaves), however, IBA did significantly increase ($P < 0{\cdot}05$) the amount of anthocyanin formed.

The anthocyanins in the leaves of *Acer rubrum* cuttings have been identified, by paper chromatography techniques, as cyanidin glycosides in agreement with Lawrence *et al.*[1]. The correlation between leaf anthocyanin content and root number on *Acer rubrum* cuttings indicates that some of the factors involved in anthocyanin biosynthesis may also be involved in root formation. Sucrose[2,3] and purines and pyrimidines[4] have been shown to promote anthocyanin biosynthesis in some tissues. Thimann and Radner have suggested that riboflavin may play a

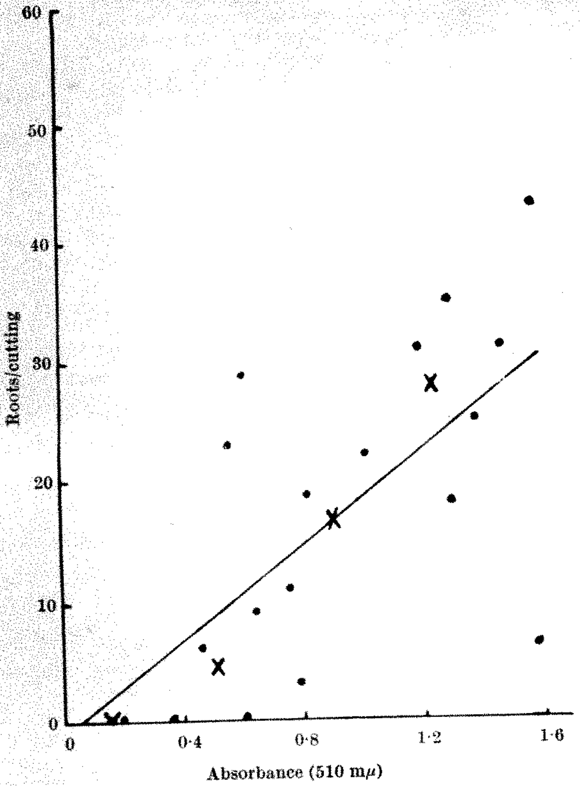

Fig. 2. Relation between anthocyanin content of the leaves (estimated from the absorbance of 510 mμ of a 0·1 *N* hydrochloric acid extract) and number of roots/cutting of *Acer rubrum*. The line drawn is the least squares estimate. The leaves of the cuttings were classified subjectively into four colour classes, as in Fig. 1, before extraction of the anthocyanin. *X* denotes the mean absorbance of extracts of the leaves in each colour class plotted against the mean root number on cuttings in each class. Cuttings from seedlings grown under continuous light. $r = 0{\cdot}677$ ($P < 0{\cdot}01$)

main part in anthocyanin formation[5]. A number of investigations[6–8] have indicated that sucrose and nitrogenous compounds, both organic and inorganic, affect the rooting of cuttings.

Basal pretreatment of *Acer rubrum* cuttings with either sucrose (4 per cent) or with riboflavin (0·1–10·0 mgm./l.) for 24 hr. prior to placing the cuttings in the rooting solution of 1·0 mgm./l. IBA did not enhance rooting of these cuttings. However, some preliminary experiments indicated that both riboflavin and sucrose may promote rooting of *Eucalyptus camaldulensis* tip cuttings. An experiment to test this possibility further yielded the data summarized in Table 1. Sucrose by itself but not riboflavin alone promoted the rooting of *E. camaldulensis* tip cuttings in this experiment. The interactions sucrose × light conditions, riboflavin × light conditions, and riboflavin × sucrose were all significant ($P < 0{\cdot}05$).

Table 1. EFFECT OF RIBOFLAVIN AND SUCROSE ON THE ROOTING OF *Eucalyptus camaldulensis* TIP CUTTINGS

Mean roots/cutting (17 days after treatment) (8–10 cuttings/treatment)

	Cuttings from seedlings grown under Continuous light		16-hr. light period	
Sucrose %	0	4	0	4
Riboflavin (mgm./l.)				
0	18·2 ± 4·30*	24·6 ± 4·88	19·4 ± 4·17	10·6 ± 3·72
0·1	26·4 ± 4·60	31·6 ± 5·32	14·4 ± 5·58	12·4 ± 2·98
1·0	12·5 ± 3·81	26·6 ± 6·02	10·3 ± 4·05	23·9 ± 5·04
10·0	19·5 ± 3·65	46·0 ± 4·92	10·0 ± 3·77	17·4 ± 3·51

* *S.E.* of the mean; *M.S.* error (whole experiment) = 183·5.

Treatment with 4 per cent sucrose + 10 mgm./l. riboflavin significantly increased ($P < 0{\cdot}01$) the number of roots formed on cuttings taken from seedlings grown under continuous light. In cuttings taken from seedlings grown under 16-hr. light period the number of roots formed after treatment with 1·0 mgm./l. riboflavin + 4 per cent sucrose was significantly greater ($P < 0{\cdot}05$) than the number of roots formed after treatment with sucrose alone.

Limited subjective evidence indicated that riboflavin may also promote anthocyanin formation in *E. camaldulensis* leaves.

These results indicate that a link between anthocyanin biosynthesis and root formation may exist. This possibility is supported by some observations from the literature. van Overbeek and Gregory[9] found that cuttings from a white-flowered variety of *Hibiscus* were much more difficult to root than cuttings from a red-flowered variety. *Spirodela* and *Lemna*, the only anthocyanin-forming genera in the Lemnaceae, are also the only genera in this family with roots[10]. Other evidence that anthocyanin-like materials may play a part in the growth of plant tissues is provided by the identification of leucoanthocyanins as one of the growth active components in coconut milk[11].

These observations combined with ours suggest that further attention should be paid to possible interrelations between anthocyanin formation and the rooting process.

Experimental Lathyrism in Turkey Embryos

LATHYRISM was first produced experimentally more than a quarter of a century ago (Geiger *et al.*, 1933) by feeding rats seeds of the flowering sweet pea, *Lathyrus odoratus*. Since then various chemicals have been tested for their lathyrogenic activity including semicarbazide hydrochloride, the drug used in this experiment.

The lathyrogenic effect of semicarbazide given by yolk-sac inoculation has been investigated mainly in chick embryos[1–8]. This experiment deals with the

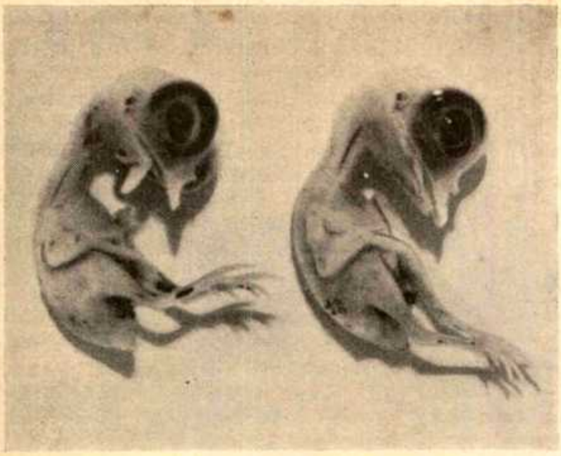

Fig. 1. Turkey embryos one week after inoculation. Note the beak deformity of the test animal

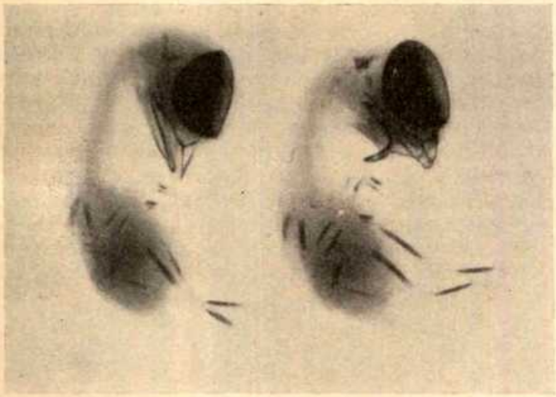

Fig. 2. Alizarin red specimen of the embryos shown in the previous photograph. The 'L'-shaped deformity of the lower beak is more evident

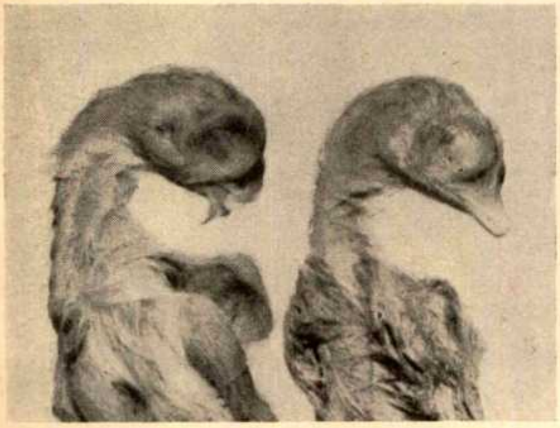

Fig. 3. Photograph of turkey embryos two weeks after yolk-sac inoculation. The beak deformities are more marked

resultant abnormalities produced by semicarbazide yolk-sac inoculation of fertile turkey eggs.

Fertile turkey eggs were placed in a Curfew electric observation incubator at 37·5° C. On the 6th day of incubation 2 mgm. of semicarbazide hydrochloride in 0·2 ml. solution was inoculated into the yolk sac. Control experiments using 0·2 ml. normal saline were also performed. On the 14th day of incubation the embryos were collected (Fig. 1). It will be seen that the only obvious abnormalities are in the beak and cervical spine. There was a slight lateral scoliosis of the cervical spine and a bilateral L-shaped deformity of the lower beak as well as an asymmetrical twisting of the upper beak. These skeletal changes are better seen in the alizarin red specimens (Fig. 2). Changes in the beak were more marked by the 21st day (Fig. 3), but no gross bending of the tibia and fibula was noted, although there was occasional dislocation of the tibio-tarsal joints. Another feature was the presence of a pseudo-umbilical hernia. No abnormalities were noted on histological examination of the skeleton or aorta.

ENTOMOLOGY

Susceptibility to DDT of Previously Resistant Nymphs of the Sugar-cane Froghopper (*Aeneolamia varia saccharina* Distant)

It has been noted in field trials conducted over a three-year period that nymphs of the sugar-cane froghopper (*Aeneolamia varia saccharina* Distant), derived from populations of the insect which have been resistant to chlorinated hydrocarbons for the past five years, are now once again susceptible to DDT (5 per cent in ground limestone). The unusual toxicity curves, a typical example of which is presented in Fig. 1, are worth mention because they differ from the original toxicity curves for susceptible froghopper nymphs, in which DDT invariably caused a quicker initial kill of nymphs[1]. A brief description of the procedures used in the experiments will facilitate the interpretation of results.

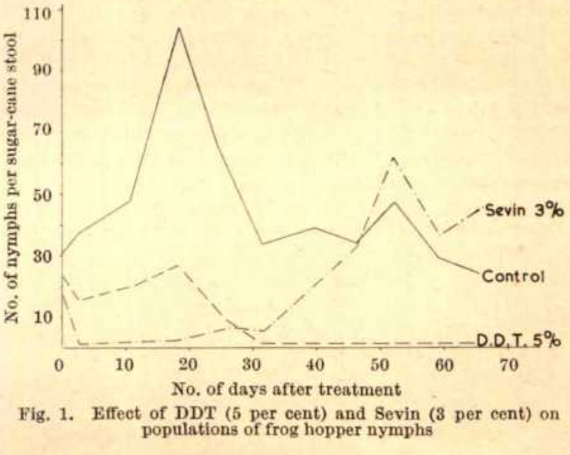

Fig. 1. Effect of DDT (5 per cent) and Sevin (3 per cent) on populations of frog hopper nymphs

Insecticides to be evaluated were formulated in ground limestone and applied as dusts to the soil surface immediately surrounding the base of sugar-cane 'stools'. It is in this area that froghopper nymphs abound. Preliminary counts of nymphs prior to application of insecticides gave an indication of the severity of infestation. The majority of nymphs present at the time that insecticides were applied were in 3rd–5th instar stages. Subsequent counts at intervals after application of insecticides provided information on 'initial' kill of nymphs as well as efficiency of control of succeeding broods. Insecticides were applied with 'Rotver' knapsack dusters at the rate of 2½ cwt. per acre of 5 per cent DDT and 3 per cent Sevin (*N*-methyl-1-naphthyl-carbamate). Randomized blocks with plots 1/40th of an acre were used with at least five sugar-cane 'stools' per plot sampled at each date of observation. Nymph populations in controls reached a peak nineteen days after the experiment was begun (Fig. 1). However, in other experiments the peaks of population densities varied depending on the time of year that the experiments were initiated. Sevin maintained a low count (less than 5 nymphs per stool) up to nineteen days after application (Fig. 1). This is significant, particularly since the population of nymphs in controls was at its height at this particular time. DDT, on the other hand, provided a slow initial destruction of nymphs. Some degree of insecticidal activity was evident especially if the numbers of nymphs in controls are compared with those in DDT-treated areas (Fig. 1). Forty and fifty-five days after application it became quite clear that DDT had controlled succeeding broods of nymphs, while this was not the case in plots which had been treated with Sevin. Nymph counts had also risen in control areas.

One may conclude that froghopper nymphs are susceptible to DDT. However, there appears to be a 'selective' tolerance of nymphs to the chlorinated hydrocarbon. Those nymphs in more advance instar stages (3rd–5th), which happened to be present when the insecticide was applied at the beginning of the experiments, were less susceptible to DDT than younger instars (1st and 2nd), which were the first stages to emerge in the successive broods. From a theoretical point of view it would be of interest to determine whether the more advanced nymphs possess a DDT-dehydrochlorinase system of the type described by Sternburg, Kearns and Moorefield[2] in the housefly. From a practical point of view it is of value to record that froghopper nymphs are again susceptible to DDT after a lapse of nearly five years, during which time other types of compounds have been used to combat the insect.

Combinations of DDT (5 per cent) with more rapidly acting compounds (such as Malathion 5 per cent or Sevin 3 per cent) should prove of value as a practical control measure, particularly in view of the effective residual action of DDT. The results also suggest that rotation of insecticides of different chemical structure might be a useful practical measure in the long-range battle against the froghopper and other insects.

A Celloidin Impression Technique for Recording Egg Sculpturing in *Aëdes* Mosquitoes

SCULPTURE patterns of the eggs of mosquitoes have been used for identification of closely related species by Horsfall, Miles and Skoatch[1] and Craig and Horsfall[2,3]. The technique used by these authors was outlined by Craig[4]. It involved first the removal of the exochorion by abrasive action followed by the bleaching of the endochorion. The endochorionic patterns revealed by these treatments were recorded by phase contrast photography.

During my recent investigation of the egg coverings of the mosquitoes of the genus *Aëdes*, it was observed that the exochorion carried surface markings identical with those occurring on the endochorion. This is not surprising: both layers are secreted by the same follicular cells of the ovary and presumably the exochorion is moulded over the preformed endochorion. However, owing to the pigmentation of the endochorion the markings of the exochorion were not obvious in the intact egg, and it was not possible to remove a strip of this fragile layer large enough to show a complete pattern. These difficulties were overcome by the use of celloidin films, which were applied to obtain impressions of the exochorionic markings.

A selected egg with the exochorion intact is orientated on a microscope slide on the stage of a binocular dissecting microscope and a second slide is dipped in a 10 per cent solution of nitrocellulose[5]. Before the celloidin sets the slide is gently lowered

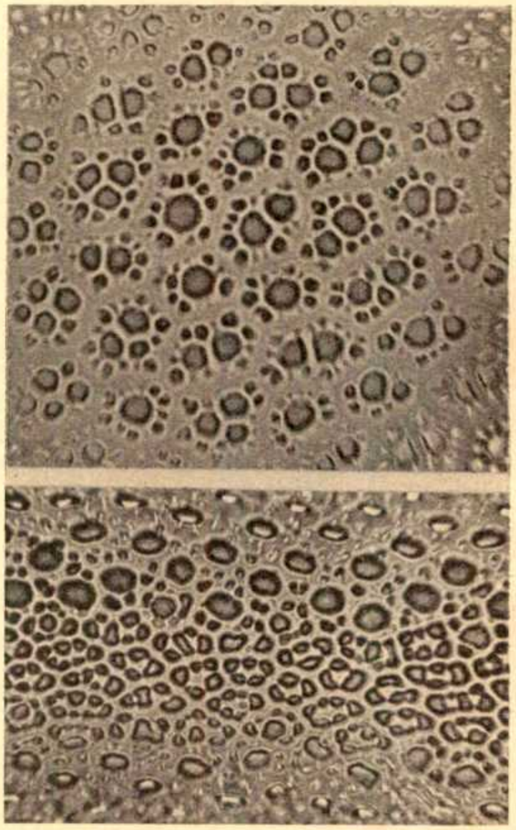

Fig. 1. Photomicrographs of celloidin impressions of exochorionic patterns. Above, *Aëdes* (*Ochlerotatus*) *alternans*, ventral (× 500); below, *Aëdes* (*Finlaya*) *alboannulatus*, ventral (× 500)

over the egg which sticks to the film. This is then hardened in 70 per cent alcohol for 1–2 min., after which the egg is removed with a fine needle. The impression left on the celloidin film remains sharply defined for 10–20 min. and can be photographed with Köhler illumination.

Observations have been made on 11 species belonging to the two subgenera *Ochlerotatus* and *Finlaya*. The sculpturing in each of the species appears to be remarkably constant, and permits accurate identification of the species. It is interesting to note that *Ochlerotatus* retains a single basic pattern over the entire surface of the egg. In *Finlaya* the sculpturing of the dorsal and ventral sides differs from those of the lateral aspects.

It is possible that the application of this technique to sculptured eggs of other insects or perhaps selected portions of their postembryonic cuticle may reveal other interspecific differences.

My thanks are due to Dr. N. Dobrotworsky, of the University of Melbourne, for identifying the adult mosquitoes used in this work.

Infestations of *Carbula pedalis* in Northern Nigeria

As there appears to be no published account of the great nuisance caused by the invasion of houses in various parts of Africa by *Carbula pedalis* Begr. (Hemiptera, Pentatomidae), this phenomenon, as observed in Northern Nigeria, together with notes on the behaviour of the species, are presented here.

The species has a general distribution between latitudes 10° and 15° N., occurring right across Africa from Senegal to the Sudan. It is, however, by no means common over this entire area and in Nigeria only the occasional specimens are found between latitudes 10° and 11° 38′ N. Infected areas are restricted to the 20–33 in. mean annual rainfall belt of the Sudan savannah, but even within this area infestation can be extremely localized. Fig. 1 gives all localities in Nigeria in which infestation of habitations is known to occur.

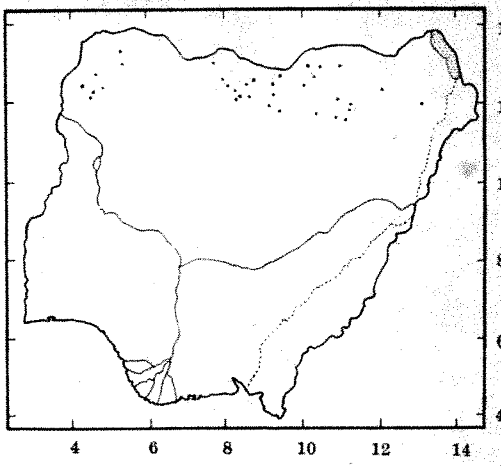

Fig. 1. Distribution of *Carbula pedalis* in Northern Nigeria

Adults start entering houses during the latter part of October or at the beginning of November at the end of the rains; the invasion period lasts for about a month. Once in a house they are strongly photophobic and tactophilic, hiding away in books, clothing, furniture, fuse boxes, under mats, among food and in nearly every conceivable niche. The smell produced by isolated individuals from the odoriferous glands is barely perceptible; but when they are present in great numbers their characteristic sickly odour is nauseating and even food becomes tainted. They can prove so troublesome that occupants of infested houses may have to vacate them at the beginning of each yearly invasion, only re-occupying them when the invasion has subsided. In some instances houses have been so badly invaded that the only remedy was to burn them down; while in one locality 12 one-gallon tinfulls were removed daily from houses during the first two weeks of the invasion period. The insects appear to show no marked preference for either thatched or non-thatched houses, and even when present in the former type they are not particularly abundant in the thatch itself. Sexing adults from various localities shows that both sexes are present in about equal numbers at both the beginning and towards the end of the indoor æstivating period (182♀, 159♂, 79♀ and 87♂). No spermatozoa were found in the spermotheca of the 40 females dissected. Fat bodies were well developed at the beginning of æstivation but diminished in size towards the end of this quiescent period.

It would appear that with the onset of the severe dry season adults seek out a more suitable environment for protection against the extreme dryness and fluctuations in temperature to which they would otherwise be subjected. Consequently houses are invaded, though more natural resting sites exist, as *C. pedalis* has been found under the barks of the trees, *Tamarindus indica* and *Ceiba pentandra*, and has been observed hanging in clusters from the fronds of the palm tree, *Borassus aethiopium*. They have also been reported sheltering in considerable numbers in hollow stumps of unidentified trees. With the onset of the rains, in April or May, they leave their æstivating sites and presumably mate and oviposit on the host plant, which is unfortunately unknown. However, the consensus of opinion among agriculturists in Northern Nigeria is that no cultivated plant is attacked by this insect.

Several methods of control have been tried in order to eradicate *C. pedalis* from houses but so far results have been disappointing. Except for one area, in which intensive residual spraying of houses has been in operation for several years, both DDT and BHC have failed to give any appreciable reductions in numbers, and this is undoubtedly due in part to the gregarious and inaccessible habits of the adults. It is, however, possible that some degree of control could be exerted by spraying with a residual insecticide prior to the invasion period, at the end of which the resident population is reduced by the application of thermal aerosols, which have the advantage of being able to penetrate into the cracks and crevices harbouring these insects.

VIROLOGY

Purification and Serology of Tulare Apple Mosaic Virus

GILMER[1], after comparing the woody host range and sap transmission of several virus isolates which caused mosaics in apple (*Malus* spp.), designated the one which could be mechanically transmitted to herbaceous plants Tulare apple mosaic virus (TAMV). Our TAMV isolate originated from a single primary lesion on the systemic host *Nicotiana tabacum* L. var. Connecticut Havana 423 inoculated with leaf tissue taken from an apple seedling bud-inoculated with TAMV stock kindly furnished by Dr. Gilmer. This isolate originated from Yarwood[2] and retained the symptomatological, host range and stability characteristics described by him.

During experiments on *in vitro* stabilization of the virus, we found that infectivity could be retained for at least 23 hr. at 25° C. by macerating leaves in an aqueous solution of 0·01 *M* sodium diethyldithiocarbamate and 0·01 *M* cysteine hydrochloride. The method of preparation of this solution had a profound effect on its stabilizing ability. Simultaneous dissolution of a mixture of the reagents resulted in a loss of stabilizing properties. Greatest stabilization was obtained when 0·02 *M* cysteine hydrochloride was added to an equal volume of 0·02 *M* sodium diethyldithiocarbamate. A pale yellow colour developed shortly after mixing and increased in intensity for about 2 hr., but the ability to stabilize was unaltered during this time.

Virus extraction was accomplished by pulverizing frozen leaves into a coarse powder at − 22° C., covering the powder with an excess of the stabilizer and infiltrating *in vacuo* at room temperature for 1 hr. Excess liquid was decanted and the tissue macerated. The crude juice was clarified by the addition of 8·5 per cent (v/v) *n*-butanol[3]. Clarified supernatants were given 2 cycles of differential ultracentrifugation in a Spinco model *L* centrifuge at 39,000 r.p.m. for 1 hr. in a No. 40 rotor. High-speed pellets were resuspended in 0·01 *M* *p*H 4·9 acetate buffer. Final solutions, representing at least a 25-fold concentration, were water clear and a marked difference in ultraviolet absorption was evident between preparations from control and virus-infected tissue (Fig. 1). The yields varied, but were in the range of 0·2–0·4 mgm. of virus for 100 gm. fresh weight tissue.

Concentrated preparations were subjected to rate density-gradient centrifugation[4] in an *SW* 25·1 swinging-bucket rotor for 2 hr. at 23,000 r.p.m. Control tubes showed no bands and contained no infectious material whereas tubes layered with the virus preparations showed a single band which was infectious on tobacco and on the local lesion host *Phaseolus vulgarus* L. var. Bountiful. When samples were removed from rate-tubes into equilibrium-tubes and centrifuged for 5 hr., a single sharp infectious band was found in the sucrose portion of the virus tubes. A faint diffuse low-density zone was also observed from both control and virus preparations in the buffer section of the tubes.

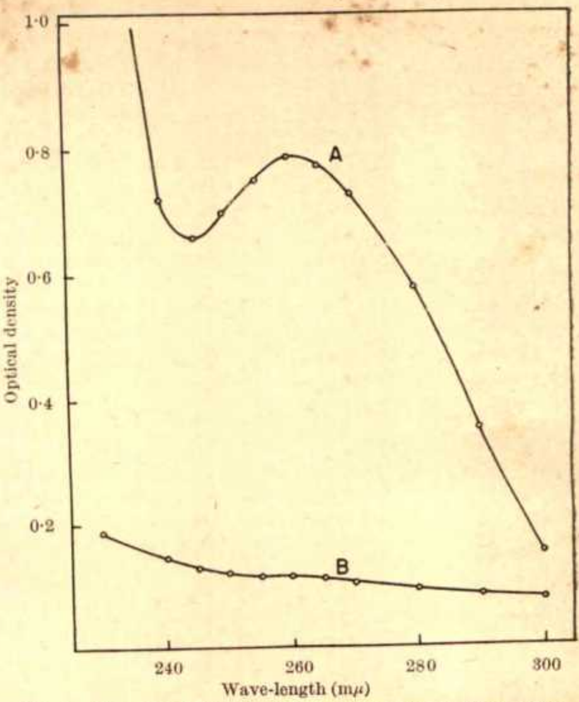

Fig. 1. The ultra-violet absorption of preparations from Tulare apple mosaic virus infected (*A*) and healthy (*B*) tobacco tissue. Curves are not corrected for light scattering

Antiserum was obtained from a previously bled rabbit injected intravenously 3 times over a 10-day period with TAMV prepared by differential ultracentrifugation and suspended in the acetate buffer. The rabbit was bled at intervals 3–16 days after the last injection and titres of 1/64–1/256 were found by the interfacial ring-precipitin test against purified virus. No reactions occurred between control preparations and antiserum or between virus and normal serum. A strong reaction occurred between antiserum and stabilized infectious tobacco sap in gel-diffusion plates, but none between the control pits (Fig. 2). Further, a faint but definite reaction

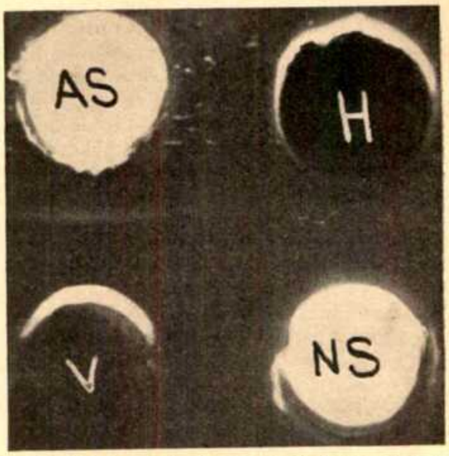

Fig. 2. Gel-diffusion plate showing precipitin reaction between antiserum (*AS*) and sap from tobacco infected with Tulare apple mosaic virus (*V*) and no reactions between control combinations. (*NS* refers to normal serum and *H* to sap from healthy tobacco)

occurred between antiserum and stabilized extracts of mosaic-infected apple leaf tissue in gel-diffusion tests.

GENETICS

Distance and Sequence of the Loci for Protan and Deutan Defects and for Glucose-6-Phosphate Dehydrogenase Deficiency

Proof for the separate localization on the human *X*-chromosome of the protanopia-protanomaly alleles and of the deuteranopia-deuteranomaly alleles requires the demonstration of: (1) non-allelic compound hemizygous males which in conditions of equilibrium should occur once among a thousand men (one in eighty colour-blind men) or of (2) cross-over males in families combining both classes of defect.

Reviving the one-locus theory, Stern[1] asserts that protan-deutan men have not been found or are at least exceptional. However, assessment of the existence and frequency of the various compound hemizygotes depends on the kind of colour vision expected of them; some could be *sui generis*, others difficult to distinguish from deutans, protans or normals. Walls and Mathews[2] consider two brothers each combining protanopic and deuteranopic features as slightly different compounds, though Stern prefers to consider them as bearers of a new allele at a single locus. Men combining features of 'red' and 'green' blindness have also been described in the older literature (see Bell[3]) and more recently by Jaeger[4]; they are indeed familiar to careful investigators. On the other hand, some such compounds are placed among the pure protans or deutans by insufficient testing, while others may have a sufficiently balanced colour vision to pass an anomaloscope test or may be sufficiently different from the ordinary run of colour-blind people not to fail on pseudoisochromatic charts. These uncertainties make one hesitate to deny the existence of protan-deutan hemizygotes and to dismiss the two loci hypothesis.

This hypothesis has recently been considerably strengthened by the publication of a pedigree by Vanderdonck and Verriest[5] containing two or possibly three cross-overs between the deuteranopia and the protanomaly genes. The family consists of the offspring from a protanomalous wife (daughter of a deuteranopic man and a normal woman) and a normal husband (son of a normal man and a woman of unknown colour vision). This union produced two deuteranopic, one protanomalous and two normal sons as well as one protanomalous and one normal daughter. The colour vision of the members of this family has been expertly investigated and their nuclear sex shown to agree with apparent sex. The authors consider the two normal sons as recombinants from the X-chromosomes of their mother, one of which carries and shows a protanomaly gene and the other a deuteranopia gene. The normal daughter is not discussed.

Before attempting an estimate of the recombination fraction between the protan and deutan genes one may ask why in spite of prolonged attempts[6] recombination has not been previously found. Women, heterozygous for protan and deutan genes, are rare (about 1 in 250), and having either near normal[7] or atypical colour vision[3,4] they can only be discovered through having a protan and a deutan son. At least a third son is needed to show recombination, but his chance to do so is less than a half. Fewer than a handful of such families had been previously described[8], and as no recombinants had been found, it was concluded that the two colour vision loci are likely to be closely linked[9]. This conclusion is no longer warranted.

The distance between protan and deutan genes may also be inferred from linkage studies including other sex-linked genes. An estimate by Haldane and Smith[10] of a recombination frequency of 9·8 per cent between 'colour blindness' and hæmophilia, which then was not clinically subdivided, seems to be based on 16 pedigrees of deutans and only one small pedigree of protans. Pedigrees combining colour blindness with muscular dystrophy are as yet not numerous. Porter, Schulze and McKusick[11] recently estimated the recombination fraction between the genes for glucose-6-phosphate dehydrogenase deficiency and that for deutan defects as 0·05 (between 0·009 and 0·18 at 90 per cent confidence-level) and the 90 per cent probability of recombination between the glucose-6-phosphate dehydrogenase gene and a protan gene as less than 0·2, and they considered their results insufficient to decide between the two loci and one locus hypotheses. However, considering Vanderdonck and Verriest's pedigree it is at present reasonable to assume that the protan locus and the deutan locus are not very close and that perhaps the locus for glucose-6-phosphate dehydrogenase deficiency lies between them, probably nearer to the deutan locus.

The position of these three loci should be considered in the linkage studies with the sex-linked blood group antigen, promised by Mann *et al.*[12].

An Unusual Bi-paternal Litter in Sheep from a Natural Double Mating

Although it is known that many cases of naturally occurring bi-paternal litters are probably born each year in domestic sheep flocks no well-authenticated examples seem to have been reported. Certainly none seems to have been studied in any detail when they

* Not available June 13, 1961.

have been seen. Apart from its value as an established case of this phenomenon, the present example is unusual in the wide diversity of the genotypes involved and the small but significant array of characters it has been possible to observe in this very mixed family group.

During the night of October 21–22, 1957, a single Merino (imported in May, 1955, from the 'Valleyfield' stud in Tasmania) entered the field where a pure dark brown Soay (from the Duke of Bedford's flock at Woburn Abbey) was being mated to a small group of white Soay × Wiltshire F_1 ewes. This unwanted occurrence was reported and confirmed on the morning of October 22, and the identity of the only Soay × Wiltshire ewe then in œstrus noted. She had been clearly marked by both the Soay and the Merino ram and, when seen, was still the object of their joint attentions. Thus a normal record of the mating as an experimental mishap was made at the time in expectation of either of the two possible crosses in any ensuing progeny.

Toward the expected date of lambing the particular ewe was closely watched and, on the morning of March 17, 1958, she gave birth to triplets after a gestation period of 146 days. First, two white male lambs were born (birth weights: 7·0 and 6·5 lb.), both of an obvious Soay phenotype except in colour. These were followed by a larger white female lamb (birth weight: 8·75 lb.) whose phenotype strongly resembled a Merino. The parturition occurred in isolation in the field, was the only one recorded that day, and, being actually observed throughout, any risk of cross-mothering or of mistaken identity was absent.

As the litter grew to maturity all three remained white and all displayed the characteristic horn-type of the Soay which the dam also possessed. The two male members are remarkably similar in general appearance and in the first series of other characters observed. The female triplet differs most noticeably from her half-brother in growing a non-deciduous fleece with a short, uniform, well-crimped staple of a distinctive Merino cross-bred type but showing such a marked dorso-ventral growth gradient that the ventral body surface is almost bare, like the Wiltshire and the Soay breeds. In 1960 and 1961 her fleece weights have been 4·5 and 5·0 lb. respectively while rearing Merino back-cross progeny on each occasion. No fleeces have been recovered from the two males, which have displayed synchronous fleece shedding each year according to the Wiltshire and Soay pattern.

On September 5, 1958, all members of the litter were sampled by skin biopsy, the parental animals having been similarly examined on other occasions. On December 8, 1958, all six members of this complex family were bled for an estimation of biochemical blood characters. The skin biopsy specimens were evaluated by the methods of Carter and Clarke[1]; the hæmoglobin types by paper electrophoresis according to the technique of Harris and Warren[2]; the red blood cell electrolytes, K^+ and Na^+, by the method of Evans[3] using an EEL flame photometer. On May 1, 1961, reciprocal whole thickness skin homografts using the Carter biopsy punch (with autograft controls on each animal) were exchanged between the two male members of the litter to test the remote supposition that these may just possibly have been one-egg twins. This hypothesis was shown to be untenable by the mutual rejection of the homografts with some asymmetry of response (8 versus 14 days). More recently, on June 13, 1961, this genetic dissimilarity was confirmed by the identification of the serum beta-globulin types (symbol *Tf*, Table 1) by starch gel electrophoresis using the discontinuous buffer system of Poulik[4], hydrolysed starch from Connaught Medical Laboratories, Toronto, Canada, and the notation of Ashton[5]. Thus all three members of the litter are from three separately fertilized eggs and the segregation of characters may be interpreted accordingly.

From this brief report it is clear that what began as an experimental mishap is now well established as an authentic case of bi-paternity in sheep of a particular kind which well displays genetic segregation for a series of characters not commonly seen among contemporaries in the same family, and certainly unusual among members of a single litter. The influence of the Merino genotype is particularly well shown in the characters of the follicle population and continuity of fibre growth in the female triplet compared with those of the deciduous pelage of the two male non-Merino phenotypes differentiated and reared under similar uterine and postnatal environments. The genetic value of suitable combinations of morphological, biochemical, and immunological criteria is also clearly evident in this case. Other experimental possibilities are not difficult to visualize if a suitable method for producing such mixed litters can be established, exploiting present superovulation and transplantation techniques with fertilized ova or even by natural service under suitable conditions.

We are indebted to Dr. J. G. Hall of this Organisation for his identification of the hæmoglobin types and the serum β-globulins; and to Dr. E. J. Butler of the Moredun Institute, Edinburgh, for estimating the red blood cell electrolytes.

FORTHCOMING EVENTS

Monday, April 16

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Dr. L. G. C. Pugh and Mr. Barry Bishop: "Man at High Altitude".

Society of Chemical Industry, Pesticides Group (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Eighth Annual General Meeting.

Monday, April 16—Wednesday, April 18

British Society of Soil Science (in the New Lecture Theatre, London School of Economics and Political Science, Houghton Street, Aldwych, London, W.C.2)—Meetings on "Productivity and Soil Type" and "Soil Microbiology".

Tuesday, April 17

British Occupational Hygiene Society (in the Physics Lecture Theatre, Birkbeck College, Malet Street, London, W.C.1), at 9.30 a.m.—Conference on "Carbon Monoxide".

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W.C.2), at 5 30 p.m.—Mr. G. Syke and Mr. C. Burns: "The Use of Closed-Circuit Television for Inspecting Fast-Moving Surfaces".

Tuesday, April 17—Wednesday, April 18

British Computer Society, and the Northampton College of Advanced Technology (at the Northampton College of Advanced Technology, St. John Street, London, E C.1), at 9.30 a.m daily—Conference on "Automatic Programming Languages for Business and Science".

Borough Polytechnic, Division of Metal Science (at Borough Road, London, S.E 1), at 10 a.m. daily—Symposium on "Automation in Metal Finishing".

Institute of Biology (in the Fyvie Hall, The Polytechnic, 309 Regent Street, London, W.1), at 10 a m. daily—Conference on "The Training of Biologists".

Wednesday, April 18

Institution of Electrical Engineers, Supply Section (at Savoy Place, London, W.C.2), at 2.30 p m. and 5.30 p.m.—Discussion on "Automation in the Supply Industry".

Worshipful Society of Apothecaries of London, Faculty of the History of Medicine and Pharmacy (at Apothecaries Hall, Blackfriars Lane, London, E.C.4), at 5 p.m.—Lord Cohen of Birkenhead; "James Carson, M.D., F.R S., of Liverpool"(Gideon de Laune Lecture).

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer or Assistant Lecturer in Theoretical Physics—The Registrar, The University, Manchester 13 (April 14).

Assistant Lecturer in Philosophy—The Registrar, The University, Keele, Staffs (April 23).

Lecturer (with a special interest in teaching and research in applied mechanics) in the Department of Mechanical Engineering—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (April 27).

Demonstrator (graduate, with qualifications in dairying and dairy microbiology) in Dairy Science—The Registrar, University College of Wales, Aberystwyth (April 28).

Research Fellow (organic chemist with a Ph.D.) in the Department of Chemistry, for work in connexion with the development of organic dyes—The Registrar, The Manchester College of Science and Technology, Manchester 1 (April 28).

Lecturer in Mathematical Statistics—The Registrar, The University, Manchester 13 (April 30).

Lecturer in Pure Mathematics—The Secretary, The Queen's University, Belfast (April 30).

Lecturer or Assistant Lecturer (with research interests in low temperature or solid state physics) in Physics—The Registrar, The University, Manchester 13 (April 30).

Lecturer (with research or industrial experience in automatic control and/or engineering systems design, and preferably a knowledge of digital and/or analogue computing techniques) in the Department of Electrical Engineering—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (April 30).

Temporary Lecturer (with a higher degree in zoology and preferably some teaching experience in comparative physiology) in the Department of Zoology and Comparative Physiology—The Deputy Registrar, The University, Edgbaston, Birmingham 15 (April 30).

Staff Tutor (with a good honours degree, preferably in one of the biological sciences, although geology will also be considered) in Science in the Department of Adult Education—The Registrar, The University, Hull (May 1).

Research Assistant (with a degree in botany, biochemistry, microbiology or genetics, and special interest in genetics, cytology, or cellular metabolism) in the Department of Botany (Prof. D. Lewis)—The Secretary, University College, Gower Street, London, W.C.1 (May 4).

Lecturer or Assistant Lecturer in Sociology in the Department of Social Studies—The Registrar, The University, Leeds 2 (May 7).

Senior Lecturer or Lecturer (medical graduate) in Anatomy at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, May 10).

Reader in Animal Husbandry and Hygiene at the Royal Veterinary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 14).

Senior Lecturer or Lecturer (preferably experimental physicist interested in the development of rocket-borne equipment for upper atmosphere and space research) in Physics at the University of Adelaide—The Registrar, The University of Adelaide, Adelaide, South Australia (May 15).

Senior Lecturer or Lecturer in Physics at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, May 30).

Lecturer in Psychology at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, May 31).

Senior Lecturer or Lecturer in Marine Biology, to work at Portobello Marine Biological Station (University of Otago), Dunedin—The Director, Portobello Marine Biological Station, Box 8, Portobello, Dunedin, New Zealand, or The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (June 30).

Assistant Professor (with a Ph.D. degree or equivalent, with teaching specialization in European geography—U S S.R. or physical geography, especially climatology) in Geography—Prof. T R. Weir, Head of the Department of Geography, University of Manitoba, Winnipeg 19, Manitoba, Canada.

Electron Microscope Technician (female) in the Biophysics Department—The Secretary, University College, Gower Street, London, W.C.1, quoting Ref. BioPh./2.

Lecturer in Electrical Engineering (Grade II), both in power and radio subjects—The Registrar, The University, Bristol 8.

Lecturer (preferably with a good honours degree and postgraduate experience of research) in Zoology—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3.

Research Assistants (graduates in physics, chemistry or metallurgy), for programmes in metallurgy and polymer physics—The Registrar, The College of Aeronautics, Cranfield, Bletchley, Bucks.

Research Students in Physics, for work in the following topics: magnetic resonance of the solid state, gas discharge studies, investigations of defects in glass and other fibres, and studies on the properties of oxide cathodes—The Registrar, The University, Keele, Staffs.

CONSERVATION OF NATURE IN BRITAIN

IN opening a debate in the House of Lords on February 28, directing attention to the recent report of the Nature Conservancy*, Lord Shackleton initiated what Lord Hailsham afterwards agreed was the first debate of any length in either House of Parliament on the Conservancy. Lord Shackleton pointed out that something like half the income of the Conservancy was spent on research, but the main emphasis of his speech was on the necessity for an ecological approach to the whole problem of conservancy and the vital importance of public understanding and co-operation if the work of the Conservancy was to be effective. He was concerned also that the resources available to the Conservancy were inadequate and that in consequence it was unable to make any really effective attack on many problems with which it was confronted or even to embark on publicity on a sufficient scale to ensure public support. He instanced in particular the lack of effort to protect the public interest in such matters as the use of toxic chemicals, provision of advice for the Department of Technical Co-operation on nature conservation in Africa, and the waste of public money in certain matters, such as the bounty given for the destruction of grey squirrels in the absence of adequate investigation.

This concern about adequate financial resources and staff and about public co-operation was freely expressed by other speakers in the debate, for example, by Lord Forbes, Lord Wilmot of Selmeston, Viscount Massereene and Ferrard. Lord Methuen strongly urged the ecological aspect, referring particularly to the international aspects of conservation, as did Lord Douglas of Barloch, Lord Chorley and the Earl of Northesk, and Lord Walston stressed the need for greater co-operation and co-ordination between the Conservancy, the Agricultural Research Council, the Council for Scientific and Industrial Research, and the Medical Research Council as well as with the universities. He also referred specifically to the question of oil pollution, and expressed the hope that the Conservancy would take a strong line at the Inter-governmental Maritime Consultative Organization's Conference on this subject on March 26, and that international agreement would be reached which would prevent this serious menace to wild-life, especially birds, through the disposal around Britain's shores of vast amounts of oil. There was general concern over the use of toxic chemicals in agriculture and also for spraying roadside verges.

Lord Hailsham, in replying as Minister for Science, pointed out that since 1955 the grant to the Nature Conservancy had increased from about £200,000 to £535,000, and in 1962–63 was likely to be £590,000, and he did not doubt that it would continue to increase until it eventually reached its optimum. Lord Hailsham fully recognized the importance of education and public relations in the work of the Conservancy, especially in conservancy, and it was because of this dependence on co-operation with the farming community, the local authorities, landowners and bodies like the Wildfowl Trust as well as with the general public that its constitution differed from that of the other Research Councils. The difference was reflected in its annual report which, Lord Hailsham claimed, was not only larger but also had a wider appeal than those of the other Research Councils.

Up to now, 95 nature reserves, covering 180,000 acres, had been declared in Great Britain, out of the 250,000 acres spread over 140 reserves in the original programme, and as this programme approached completion the Conservancy should be able to concentrate increasingly on research and advisory work, and Lord Hailsham was particularly anxious to encourage the Conservancy, within its resources, to build up its ecological research. In this connexion he stressed the long-term character of the work, instancing that on woodlands and population dynamics and coastal erosion. As regards the use of toxic chemicals in agriculture, he said that the new experimental station at Monks' Wood would be undertaking work on the effects on wild-life and the natural environment. He fully supported the recommendations of the Select Committee on Estimates for increased research grants to universities and other institutions, and the Conservancy's expenditure on such research grants had risen from £9,000 in 1954–55 to £29,000 in 1960–61, and the grants were intended both to foster ecological research and a more comprehensive teaching approach, as well as advanced training in conservation. Lord Hailsham indicated that he expected later this year the report of the Committee which, under Sir William Slater, was reviewing the present organization of research in fisheries, forestry, hydrology and other subjects, and he thought that the biological subjects were probably on the verge of great developments which might well transform them in the next fifty years as the physical sciences had been in the past half-century. We must make sure that our organization of scientific research is such as to encourage developments in Great Britain adequate in scale and quality to permit speedy growth and exploitation.

Lord Hailsham referred to the serious effects of the use of herbicides on the flora of roadside verges and claimed that the work of the Conservancy had spared us from the worst features of the destruction that had occurred in other countries. On the question of international conservation, while he gave no indication of the scale of support through the Department of Technical Co-operation or of its adequacy, he fully recognized the value of the Conservancy's contribution. The Conservancy had been prominent in planning the work of the International Union for the Conservation of Nature, particularly the African Special Project, and he thought that this international co-operation was bearing fruit in the constructive attitude of the emerging countries of Africa. If he did not altogether satisfy Lord Shackleton as to the adequacy of the financial resources at the disposal of the Conservancy, so far as international co-operation is concerned, Lord Hailsham said enough to suggest that the Department of Technical Co-operation should be able to count on his sympathy and support if it finds it necessary to ask for greater help and resources to be made available for that purpose.

---

* Report of the Nature Conservancy for the year ended 30th September, 1961. Pp. vii+114+14 plates. (London. H.M.S.O., 1961.) 8s. 6d. net.

In his reply, Lord Hailsham also referred to the question of hydrological research which had been specifically mentioned by Lord Shackleton and also by Lord Walston, who was concerned that hydrological research was being held up by shortage of funds, particularly against the background of conservation policy generally. Lord Shackleton had pointed out that we now had to face the consequences of a decision taken in an earlier debate on February 8, to strike out of the Manchester Corporation Bill the part which permitted the Corporation to obtain water from Ullswater. The decision implied that water, and the demands for it, must not be treated in isolation from the other needs of the community. Lord Shackleton said that he was wholly in sympathy with the decision of the House as related to the amenity factors of Ullswater, but Britain's supplies of water were not unlimited and within the next thirty years we would almost certainly have to seek water sources other than fresh water.

The decision on Ullswater thus accentuated the need for hydrological research, to which some reference is made in the Nature Conservancy's Report. The Interdepartmental Hydrological Research Group has been disbanded and replaced since April 1961 by the Committee on Hydrological Research, but the Conservancy is already engaged in investigations in extensive watershed areas, and, in view of its specialized knowledge on biological and physiographical aspects, quite rightly holds that it would be in the interests of economy and efficiency for them to make the necessary investigations into these aspects, while, on the other hand, they are not competent to conduct studies into engineering and physical aspects, which are of equal importance. Discussions are continuing with the view of deciding how best a research programme should be drawn up and implemented, and the Conservancy has already urged at a conference last June of the British Waterworks Association that foresight and co-operation were required if competing claims to the use of water were not to lead to friction and wise policies were to be widely accepted.

The Conservancy observes in this annual report that, although some experiments are being pursued, money is needed for adequate scientific research, and it seems that the concern which Lord Shackleton and Lord Walston expressed as to whether the Conservancy had adequate funds at its disposal to implement urgently needed research on a sufficient scale in this field is well founded. On this point the Minister for Science was not entirely reassuring. He agreed that we have to learn more about the factors affecting our water supplies if we are to make the best use of them and pointed out that the Committee on Hydrological Research brought together the various interests and bodies with special responsibilities here, including the Geological Survey, the Meteorological Office and the Hydraulics Research Station of the Department of Scientific and Industrial Research, as well as the Nature Conservancy. The latter's special contribution was in the study of the influence of different forms of land use and land management on the evaporation and run-off elements in the hydrological cycle. The Conservancy was conducting investigations and experiments in the extensive watershed areas and was providing staff for a new Catchment Research Unit to be established initially at the Hydraulics Research Station at Wallingford.

If this debate brought out the critical importance of taking a comprehensive view of demands made on national resources—Lord Hailsham himself admitted the need for a co-ordinating Minister in respect of hydrological research—the earlier debate on the Manchester Corporation Bill also emphasized the need for greater co-operation and co-ordination. The issue in that debate was not so much whether the part of the Bill relating to waterworks should be approved or not—these clauses were almost unanimously opposed—but whether they should be deleted forthwith or examined in detail at the committee stage. It was not in dispute that the Manchester Corporation must get more water from somewhere if the situation by 1970 was not to become critical: the issue was rather whether the promoters of this Private Bill should be allowed to present their case to a Committee of the Whole House where the issues could be fully and expertly and impartially examined, though in practice this would be mormally limited to the arguments presented by the promoters.

Opponents of this part of the Bill—the only part which was opposed—did not always recognize the extent to which the Manchester Corporation had sought to meet its critics and ensure that the scheme did as little damage as possible, but this is not really relevant to the major issue any more than is the alarm caused by the impression of haste and secrecy which was conveyed to some by the way in which the scheme was handled by Manchester authorities. The real issue is that a single waterworks authority, however important, should be able to advance an independent proposal threatening to spoil a particular national interest—that of amenity in a national park—and it is made the more intolerable by the admission that the proposal offers only a temporary solution and that ultimately resort must be had to distillation of sea-water or like means. As the late Lord Birkett emphasized, in what was possibly the decisive speech in the debate, we should be assured that really serious search had been made for alternative sources before proposals involving a national park were advanced, and full explanation and reason should be given for the rejection of alternatives. Such a proposal should only be possible on the basis of a national water policy and of an authoritative survey of water resources and of future demand. The decision should be a national decision and not one advanced by any individual authority or on Departmental judgment.

This view was cogently argued by Lord Silkin, who was prepared to let the clauses go forward for examination in committee, and by Lord Rea, and, as was pointed out by Lord MacAndrew, it is a principal conclusion of the Central Advisory Water Committee's sub-committee's final report on the growing demand for water that it should no longer be left to independent initiatives to develop Britain's water resources according to their separate needs. "A separate central authority, accountable to the Minister, should be set up to promote an active policy for the conservation and proper use of the country's water resources." The sub-committee saw no reason to doubt that the rainfall in England and Wales is sufficient to ensure an adequate supply of water to all parts of the country provided proper means of conservation and distribution are developed to keep pace with growing demand, and while Prof. Gordon Manley has expressed the view that ultimately it may be necessary to meter all supplies, he considers that in the meantime the proposed regional authorities will supply a much-needed organization.

The core of the situation is that water is now far more than a local problem, and, as the sub-committee concludes, it should no longer be left to independent initiatives to develop the country's water resources according to their separate needs. That is made equally plain in the debates on the Manchester Corporation's Bill and the Nature Conservancy. The future of Ullswater, alike from the point of view of amenity and of water supply, is a national matter and should be treated as such. The Minister of Housing and Local Government has rightly asked for reasonable time to study the report on water supplies which was only published a week before the debate, and, while the sub-committee considered anything in the nature of a national water grid was impracticable, its recommendation for the creation of new river authorities to manage the water resources of river basins as a whole, and responsible for the preservation, control and development of water resources, both surface and underground, by storage and other means, would prevent the recurrence of such a situation as was created by the Manchester Corporation Bill. Much would, of course, depend on the resources, as well as the powers, available to the proposed authorities; some provision is clearly required for reconciling impartially other national interests, such as amenity, where they clash with the national need for water and ensuring that cost is considered on a national and not a local or even regional basis.

Again, if such alternative sources of supply as the distillation of sea-water or the re-use of water by industry are to receive fair consideration, adequate resources for investigation must be available, and this should reasonably be a national charge. Prof. E. D. Howe, director of the Salt Water Conversion Laboratory of the University of California, recently expressed the opinion that in spite of substantial improvement in costs and in the performance of desalting equipment effected in the past ten years, basic scientific and engineering investigations were badly needed into existing and hitherto unused processes for obtaining fresh water from sea-water. Two British companies already specialize in such plant and between them have installed most of the world's land-based sea-water converters, but cost is clearly recognized as a major difficulty, though it is believed that the cost could be reduced to 2*s.* per 1,000 gallons within five or ten years, particularly if the Government assisted with development contracts. There is no prospect of a revolutionary method of obtaining fresh water from sea-water at a negligible cost.

Meanwhile, the Minister of Housing and Local Government has agreed to call a conference of authorities which are directly affected by the proposals of Manchester regarding Ullswater and Bannisdale to consider how the need for additional water supplies for the Manchester region can be met, and over this Conference the Parliamentary Secretary to the Ministry, Lord Jellicoe, is to preside. At a conference in Manchester on March 5 of nine water authorites which take water in bulk from Manchester, a technical working party was appointed to study the water supply situation in the north-west region, and it is hoped that the preliminary views of this working party will be available for Lord Jellicoe's conference. Even more important, however, is an early Government decision on a national water policy and the precise means by which such a policy should be implemented.

In replying on the debate in the House of Lords on February 8, the Minister for Science seemed to lean to an investigation of the situation by a Select Committee, particularly in regard to alternative sources of water supply, though as regards the distillation of sea-water he was scarcely more encouraging than Lord Jellicoe, who merely quoted from the report of the sub-committee on the growing demand for water that while the distillation of sea-water might find some application in coastal areas in general it was likely to be more economical to transfer water from other catchments to the extent to which it was available. The use of the term economical, however, avoids the real issue, and in neither debate did the Minister for Science sufficiently emphasize the importance of a national policy in regard to national resources whether of water supply, of land, of fauna or of flora, and the futility of piecemeal decisions. Both debates in the House of Lords and the report of the Nature Conservancy itself point decisively to the urgent necessity of a national policy in such matters and as corollary to the need for an organization adequately staffed and equipped to provide the facts on which wise decisions can be made in time and not after events have taken charge of the situation.

A NEW HISTORY OF CHEMISTRY

A History of Chemistry

Vol. 2. By Prof. J. R. Partington. Pp. xxiv+795, with 38 illustrations. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1961.) 105*s*. net.

THE appearance of a comprehensive and detailed history of chemistry by Prof. Partington must be hailed as a momentous event in this important field of humanistic science. The author's reputation as an outstanding authority has been long established by his *Short History of Chemistry* and a legion of specialized papers ranging over many aspects of a vast subject. The *Short History* of 1937, reaching a fifth issue in 1960, is universally acknowledged as a masterpiece of accuracy and selective presentation; and this work has now become the harbinger of a massive and fully-documented treatment. Since the classical books of Hoefer and Kopp, dating back to the 1840's, there have been other histories of chemistry, but in general these carry no detailed references to original sources. Moreover, both the science of chemistry and research in historical chemistry have made enormous advances in recent times.

The work is to be issued in four volumes, of which the first to appear (Volume 2) traverses the period 1500–1700, marking the slow extinction of alchemy and the gradual opening of the road leading on to modern chemistry, through the era of phlogiston. Volume 3, 1700–1800, already in the press, deals with the progress of chemistry in France, Scandinavia, Germany, Great Britain and Ireland, passing through the later years of the phlogiston theory to Higgins and Dalton. Volumes 1 and 4, both in preparation, will be concerned with the earliest (to 1500) and latest (from 1800) periods.

To his formidable task the author brings the fruits of extensive reading and research. A work of this scope, marked by sound scholarship, meticulous documentation, accuracy of detail, and copious quotations from original sources, would normally call for the united efforts of a team of specialists; it is therefore amazing to find a single author producing a massive work of this character.

Space allows of the mention of only a few specific points, taken in illustration from the twenty chapters. Essentially, the treatment is based on a biographical plan, lending significance to the humanistic aspect of the subject. Chapter 1 ("Empirical Prelude") leads off with the versatile Leonardo da Vinci, followed by Eck of Sulzbach, Cardan and Porta, with sections on books of poisons and books of secrets. Of Cardan, it is related that he lost a fortune at chess, sold his wife's jewels, and acquired a great reputation by travelling in 1552 from Milan to St. Andrews and curing Archbishop John Hamilton, to the great envy of the Scottish practitioners. Chapter 2 ("Technological Treatises") tells us that Biringuccio, whose *Pirotechnia* appeared in 1540, had an extensive knowledge of metallurgy and technology, including "such politically useful branches as gun casting, the manufacture of gunpowder, and making false coin". Here, as in general throughout the volume, there is a summary of the bibliography of the author's important writings; a note on his life and career; a full documentation of leading statements; and also quotations in the original language and in English.

A detailed bibliography relating to Paracelsus (Chapter 3) illustrates the great attention that has been devoted to this vivid and blustering man, not least in modern times. Among his iatrochemical successors (Chapter 4) comes Thurneisser, a character little less picturesque than Paracelsus himself. Son of a Basel goldsmith, "in consequence of having sold a gilded brick to some Jews, he left for England in 1548," at the age of seventeen; travelling extensively, he developed into a charlatan and business man, resembling Paracelsus in "Geist und Betriebsamkeit". In this chapter it is pleasing to find mention of Mylius and Stolcius, two of many intriguing alchemical figures whom historians of chemistry have generally ignored.

"Basil Valentine" (Chapter 5) is described as, after Geber, "the literary forgery which has misled and perplexed chemists for the longest period". Dealing later with Francis Bacon and others, the author considers the development of philosophical thought in the supersession of the views of Aristotle, with their medieval accretions, by the new ideas of Bacon, Descartes and Gassendi, stressing thereby the importance of including a concise account of philosophical systems which have influenced chemistry.

Judging from the quality of the initial volume, there can be no doubt that this erudite and authoritative work will stand out as a landmark in the literature of historical chemistry. JOHN READ

SURVIVAL AND SEXUAL SELECTION

Theory of Sexual Selection

By L. S. Davitasvili. In Russian. Pp. 538. (Moskva: Akademia Nauk S.S.S.R., 1961.) n.p.

SINCE "very many biologists who work on the evolutionary problem reject the theory of sexual selection, or merely ignore it", the author has set himself the task of collecting carefully any facts which might serve to support the theory as originally formulated by Charles Darwin. Darwin's term "secondary sexual characters", as well as that of J. Huxley, epigamic characters, are considered too broad, and he proposes a category of perigamic characters defined as "such traits of the structure and behaviour of animals which arise and develop through sexual selection". A chapter is devoted to criticisms of other writers on the subject—largely Russian—though the views of Pycraft and J. Huxley are also discussed, not very favourably. In formulating the basis of his own approach to the problem, the author admits that "of course, nobody saw how species are transformed under the influence of sexual selection", but he considers it legitimate to regard as highly probable such influence in the cases when certain unusual structures cannot be explained by the requirements for obtaining food, movement or defence from enemies.

Fourteen chapters are devoted to a review of the supposed perigamic characters in a number of animal groups, with particular emphasis on the extinct vertebrates—the author being a palæontologist. Recent cephalopod molluscs, with their highly developed nervous system, colour changes of males and their fights during mating period are regarded as undoubtedly offering examples of sexual selection; more daringly, perigamic importance is postulated for the external protuberances and, especially, the ligulæ of Ammonoidea. The importance of sexual selection in the living Arthropoda (Crustacea and insects) is regarded as beyond doubt and, therefore, only a short chapter is devoted to them; recent fishes, of course, offer much support to the author's theories, but he also ascribes perigamic function to such features of fossil fishes as the spiral 'nose' of *Helicoprion*. Again, recent reptiles, with their extraordinary crests, folding collars, bright coloration, etc., serve to encourage his search for unusual structure among the fossil members of the group, and the extraordinary crests of some dinosaurs (especially the *Pelicosaurus*) are discussed at length; the views of Romer, Colbert, Yonge and others regarding possible functions of these structures are dismissed and there is no choice left but to postulate their importance for sexual selection. Armoured dinosaurs, stegosaurs, ceratopsids, etc., are treated in the same way and even the enormously thick skulls of Pachycephosauridae are regarded as perigamic characters, which would be useful during fights between males, if they had this habit.

Coming to birds, the author rejects suggestions of J. Huxley and Boback that bridge plumage of males distracts attention of enemies from sombrely coloured females and is, therefore, favoured by natural selection. Mammals, again more particularly fossil ones, offer a wealth of cases of extraordinary development of horns, tusks, etc., which are all interpreted to favour the author's views, and he criticizes severely those of J. Huxley, Simpson, Schmalhausen and Hersh who regarded such structures as a result of allometric growth and hypermorphosis.

The author's final conclusion is that "the sexual selection is merely a special form of natural selection". The book is well produced, with abundant, though not original, illustrations, and the bibliography of 20 pages includes references to some foreign and Russian papers as recent as 1960.

PATHOLOGY OF THE BANANA

Banana Diseases, including Plantains and Abaca

By Prof. C. W. Wardlaw. Pp. vii + 648. (London: Longmans Green and Co., Ltd., 1961.) 130*s*. net.

WARDLAW'S *Diseases of the Banana*, published in 1935, has until now remained unchallenged as the best available text-book on the subject; but inevitably much has happened in a quarter of a century to make it out of date. The banana industry, the plant pathologists who serve it, and all who are scientifically interested in tropical agriculture, must therefore be glad that Prof. Wardlaw has been able and willing to write a new book to replace his earlier one. He has unique qualifications for the job and has done it beautifully, combining his first-hand knowledge of developments in the field with an impressive diligence in the handling of the literature —up from 559 references in 1935 to more than twice as many to-day. Like its predecessor, *Banana Diseases* deals with the pathology of the plant in the field and of the fruit in transit from field to consumer. The post-harvest diseases and the wastage they cause in shipment occupy about one-fifth of the text.

Three chapters set the background for a detailed discussion of the various infectious diseases of the crop in the field by presenting an outline of the botany and cultivation of the banana, followed by an account of the numerous non-infectious disorders caused by unsuitable climatic and cultural conditions such as soil deterioration, poor drainage, drought and mineral deficiencies.

Of the individual diseases in the field, banana wilt, or Panama disease, still takes the most prominent place. Though controlled in practice in an increasing number of producing countries by change of variety from Gros Michel to various clones of the Cavendish Group, Panama disease continues to challenge the pathologist with baffling scientific problems of considerable economic importance. Consequently, a great deal of research has been done on it since 1935 and investigations continue. The two chapters devoted to Panama disease provide an excellent critical summary of the present state of knowledge on this subject.

Second place is now held by leaf spot, or Sigatoka disease, and the two chapters on this contain some of the most important new material in the book. They include the astonishing story of the critical years in which leaf spot suddenly threatened the survival of the trade in the Western hemisphere, and the heroic measures by which it was brought under control—probably, as the author says, one of the greatest achievements in the history of phytopathology. They also present a thorough account of subsequent improvements in control measures, including the introduction of oil spraying. It is especially in this section that the reader is made aware how far the industry has moved in recent years towards more intensive methods.

Chapters on the virus diseases, and on the lesser. but not unimportant, bacterial and fungal diseases of the plantations, are all equally up to date.

Detailed accounts of the many fruit diseases that become important after harvesting are prefaced by an outline of the processes of harvesting, packing, transport and ripening, and a chapter on the causes and extent of wastage in harvested fruit. The changes in the techniques on the handling side of the industry have been less conspicuous than those on the growing side; but there have been steady improvements, which are well summarized.

There are short but useful appendixes on nematode diseases, the weevil borer, and deterioration of Manila hemp. The book is elegantly produced, as its scientific quality deserves, and well illustrated.

E. E. CHEESMAN

HORTICULTURE: 1958 VINTAGE

Advances in Horticultural Science and their Applications

Proceedings of the 15th International Horticultural Congress, Nice, 1958. Vol. 1. Edited by Jean Claude Garnard. Pp. lxxxi + 546. (London and New York: Pergamon Press, 1961.) £20 net per set of three volumes.

INCREASINGLY, reports of international conferences are coming to be accepted as works of review and reference. In this respect a report on a horticultural congress is at a disadvantage; the subject-matter is varied in character and must cater for the interests of growers and of research workers with widely differing backgrounds. Nevertheless, if the format and price of the three volumes reporting the Horticultural Congress at Nice are to be justified, it is as works of reference that they must be assessed.

The four "general lectures" which are printed in this first volume were presumably intended to give members of the Congress opportunities to hear recognized authorities give short accounts of their own fields of work. In printed form such lectures are of more limited value and in parts read too much like potted versions of the subjects under discussion. Some interesting hypotheses and concepts concerning morphogenesis in plants are introduced by R. Bouillenne in "Hormones Végétales, Organogénèse, Sexualization et Floraison" and by S. J. Wellensiek in "Theoretical Backgrounds of Flowering". It is unfortunate that while presented in the form of short reviews these papers include no lists of references.

After the general lectures comes a series of symposia dealing with growth substances, fruit ripening, soilless culture, diagnosis and control of virus diseases, mineral nutrition, uses of plastics in horticulture and heterosis and breeding of horticultural plants. Matching this range of subjects is the range of approaches adopted by the contributors. There are critical reviews incorporating the contributor's own research findings like the papers on fruit senescence by A. C. Hulme, and on chemical control of growth and flowering by J. P. Nitsch; there are papers which are primarily experimental like those on strawberry nutrition by C. Bould and on foliar diagnosis of mineral deficiencies by P. Prevot and M. Ollagnier, and there are papers which are largely descriptive like those on "Commercial Experiences in Soilless Culture" by S. R. Robins, and on "Plastics for Horticultural Use" by E M. Emmert.

The remainder of this first volume is taken up with an impressive number of papers on vegetable crops, their culture, breeding, physiology and diseases. Here, most of the contributors present results of their own experiments, and the papers together form a valuable collection of information which, except for this publication, must have been scattered through many journals. The strong international character of the Congress is evident both in this section and in the symposia.

Although misprints can be found, the standard of production of the book is generally high, the figures and tables are very clear, and the abstracts in English, French and German which precede each contribution are a helpful feature. The table of contents would have been better placed immediately after the preface instead of after about sixty pages of information concerning the Congress; some of this might have been better in an appendix.

The delay in the publication of the proceedings of the fifteenth Congress, held in 1958, is regrettable, but regret can be tempered with relief that they have appeared before the sixteenth International Horticultural Congress takes place in Brussels later this year. G. P. HARRIS

ANIMAL COLOUR AND ANIMAL COLORATION

The Nature of Animal Colours

By H. Munro Fox and Gwynne Vevers. (Textbooks of Animal Biology.) Pp. vii + 246 + 8 plates. (London: Sidgwick and Jackson, Ltd., 1960.) 42*s*. net.

IN view of recent discoveries and important advances in our knowledge of animal colours, especially due to the application of new and improved techniques, a comprehensive survey of this field is both timely and welcome.

It is more usual to consider animal coloration in relation to the environment and its value to behaviour and survival, but with its reminders of the existence of internal colours and functions of pigments other than visible coloration, this book, concerned with the nature, origin and fate of the colours, provides a valuable corrective and so opens up wider perspectives.

Of the two categories of animal colour—structural and pigmentary—the former, dependent on the physical nature of the surface and the effects of interference, diffraction and light scattering, has a brief but adequate description, while the latter, dependent on chemical constitution in relation to absorption spectra, is dealt with in detail.

The various chemical groupings of the pigments are reviewed in turn, and this supplies information on their occurrence, structure, varieties and variations, physical and chemical characters and functions. These accounts are up to date, admirable in scope and detail, valuable for the many items of historical and general interest brought together and particularly useful not only for the information provided but also for indications of its limitations and even its complete absence.

Melanin is not the only dark pigment, as the accounts of protein tanning and the ommachromes show, and the latter are unique since genetical research was responsible for their recent discovery. The well-known tyrian purple related to the melanins is not concerned with coloration in animals as it appears in a secretion after it leaves the body. Carotenoids, widespread in animals and combined with proteins or dissolved in fats to give a variety of colours, are obtained in their food, since they cannot be synthesized by animals. They are related to vitamin A and visual pigments. Chlorophyll, the main plant pigment, is absent from animal tissues except for a few symbiotic algae, but derivatives from food form green pigments in a few animals.

Hæmoglobin, as abundant as melanin, is a blood pigment with its primary function respiratory, and only relatively few animals owe their surface coloration to its presence. The same applies to other blood pigments of more limited distribution and the differences in chemical structure are concerned more with their efficiency as oxygen carriers than colour. Colourless respiratory pigments do not appear to exist. Hæmoglobin is broken down to bile pigments. These bilins can colour the integument or internal organs of some invertebrates or calcareous structures such as birds' egg shells, gallstones or molluscan shells.

Apart from activity in the tanning of proteins and synthesis of melanins, quinones appear as pigments in echinoids and scale insects (cochineal), but little is known of their origin or function.

These few notes give some indication of the range and treatment of the subject and the successful blend of biochemistry and natural history. There is a vast amount of information and more than six hundred references are listed. The presentation is good with a style clear and precise which maintains and stimulates interest to the end. There are some fine illustrations on eight colour plates.

This book offers both teacher and student much in concise form, and with the final chapter on the study of pigments in the laboratory and the appendix giving a synopsis of animal colours should appeal, as the authors hope, to the sixth form at school and a wider circle from the naturalist to the research worker. E. A. SPAUL

THE SYSTEMATICS OF MAN*

By BERNARD CAMPBELL

"SYSTEMS do not exist in Nature, but in men's minds." This observation of the physiologist Claude Bernard is scarcely acceptable to-day, but it does emphasize the strong inclination which the brain displays to systematize subjectively. Systematics is the investigation of the order and pattern which exists in Nature, and it is not a simple matter to develop such a science on a strictly inductive basis without being influenced by preconceived hypotheses.

But this is not the only fundamental problem facing systematists. It is necessary to record precisely the system as it exists, and this is profoundly difficult to do. It is clear, for example, that a numerical symbolism is more suited than a verbal one, to continuous as distinct from discontinuous phenomena. The more continuous the data become (that is to say, the more data at our disposal) the more inadequate will appear the taxonomic verbal symbolism of binary nomenclature.

Although a number of taxonomists (for example, Mitchener[1]) and most botanists can only aim to provide a purely static or phenetic, rather than a phylogenetic or phyletic classification, as a result of the limited data available, it is clear that to be most useful a classification must carry the maximum information content, and so must, where possible, be phyletic. In the study of man we have a fossil record, and there is no reason to aim at anything less than a full phyletic classification.

Before consideration of the systematics of man, the term 'man' requires definition. Oakley[2] has defined him as the "tool-maker", and this is the most valuable definition that students of man possess. The presence of stone tools accompanying fossil discoveries is easily recognizable, and while it cannot always be certain that the men associated with the tools made them (rather than their neighbours) it is normally a safe assumption. It is, however, an ethological character, and a more appropriate definition for the purposes of this article is by a recognized taxon—the family of man—the Hominidae. This family is generally recognized to contain two genera of undoubted tool-makers—*Homo* and *Pithecanthropus*, and one further genus *Australopithecus*, the present members of which were probably tool-makers and almost certainly tool-users. Verworn[3] called tools "petrified ideas", and it can be assumed that these remarkable ideas were introduced by members of the genus *Australopithecus*. All three genera have been recognized in all three continents of the Old World with the exception of *Australopithecus*, which is not at present known from Europe.

The Hominidae are characterized by a combination of the following main evolutionary trends:

(1) Bipedalism, together with associated skeletal changes.

(2) Changes in the position of the head on the vertebral column resulting from the erect posture, and associated modifications of the face, neck and jaws.

(3) Reduction and modification of the teeth. Hands and tools replaced the use of teeth for many tasks.

(4) Fœtalization: that is, the retardation of both ontogenetic development and the onset of sexual maturity, which have resulted in a prolonged juvenile learning phase and greater plasticity of behaviour.

(5) Lack of specialization, making possible the exploitation of a variety of environments. In particular the dentition and digestion are omnivorous, and the hand versatile, and prehensile.

(6) The development of social life, tool-making and speech.

(7) The increase in the absolute and relative size of the brain, and in particular the frontal region.

In a recent publication, Huxley[4] has described the Hominidae as Psychozoans, as distinct from Metazoans. The unique quality of the human animal implied by this 'grade' name leads to consideration of the peculiar problems of Hominid, or Psychozoan, taxonomy.

Special Problems of Hominid Taxonomy

Man cannot readily investigate himself objectively. This would appear to be for two reasons: first, man projects on man a reflexion of his own psyche, and secondly, man can communicate with man, and cannot treat his fellows as non-sentient objects. The discussion which is at present current as to whether a social science is a logical possibility can equally be applied to all anthropological sciences. In a recent review, Horton[5] has written: "The differences of attitude which underlie the category barrier human–non-human are far greater than those which underlie the category barrier living–non-living". It is scarcely possible for man to investigate man or his remains with the dispassionate and objective manner that he accords non-living matter, and attempts to accord living matter. In this sense, human taxonomy is a more difficult science than most, and the difficulties have been enormously accentuated by the fact that some of those who have published their opinions on the subject in the past have received little scientific training, let alone taxonomic training.

A subsidiary problem is that the experimental method, the cornerstone of scientific investigation, cannot be applied directly to help solve the problems involved in arriving at a taxonomy of living man. Transplant experiments in botany, and the use of controlled environments in zoological studies has given a new tool to taxonomists of living forms. Studies of *Homo sapiens* are limited to observations in an environment that cannot be controlled. The science is descriptive rather than experimental.

The first stage in taxonomic research involves a judgment of overall affinity: morphological, physiological, biochemical, genetic and ethological characters are involved. The second stage involves a qualification of such judgment to assess phyletic affinity.

It is clear that in many instances judgments of morphological affinity can be made by a taxonomist by inspection without much possibility of gross error, and this is especially true when a collection of specimens represents groups related, but not too closely related. Controversy arises when the issue is less clear. Hominid taxonomy has now reached the stage when many new taxonomic judgments are controversial, and it is therefore essential that the subject should be put on a more objective basis.

---

*Substance of a lecture given before the Systematics Association on February 8 at the British Museum (Natural History).

Living Man an Animal

Man has not always recognized himself to be a kind of animal, and although Linnæus classified man with the apes in his *Systema Naturae* as Anthropomorpha, his concept of their relationship was based on phenetic similarity as had been Aristotle's when he classified man with other mammals 2,000 years earlier. It was La Mettrie in 1748[6] who not only presented a remarkable account of the similarities of man and animals, but also recognized the organic unity of Nature.

Those who accepted the idea of living man as an animal were then faced with the problem of whether he consisted of one or more zoological species. This difficulty was accentuated by lack of knowledge of the dark-skinned races of man, and by the overwhelming Biblical authority for the existence at some past moment of a single pair of human ancestors. On one hand, there was evidence of strange 'wild men', differing very much from ourselves, and on the other hand good reason for supposing that on Biblical authority we all shared a common and recent ancestry. Before the nineteenth century it took courage to suggest any deviation from the Biblical account of creation.

In his early editions of the *Systema Naturae* (1735–56), Linnæus clearly divided *Homo sapiens* into four varieties (Americans, Europeans, Asians and Africans) though in the tenth edition (1758) he adds wild men and monsters as two further sub-divisions. (At the same time he classified the orang-outan as a species of *Homo* in the tenth edition (as *Homo troglodytes*), but this species was transferred to *Simia* by the twelfth edition (1766).)

Buffon[7], writing at the time of Linnæus, was clear, too, in his mind that man originated from one species; but he believed that climate and other external factors had caused varieties to become specifically distinct in the passage of time (1749). Immanuel Kant[8], in 1775, argued that all human beings belong to the same natural species "since in mating they always beget fertile offspring however dissimilar the parents may be in appearance. For this unity of species, he wrote, "there can be but one natural cause—that all men belong to a single stock". Blumenbach[9], the father of anthropology, supported this view the same year, in his M.D. thesis.

But by the nineteenth century, the subject had become increasingly controversial and many authors, breaking free from the teaching of the Church, were arguing for a polyphyletic origin for mankind, which involved the recognition of many species derived from different pre-*sapiens* forms. Quenstedt, the famous palæontologist, wrote that "if Negroes and Caucasians were snails, zoologists would universally agree that they represented two very different species, which could never have originated from one pair by gradual divergence". But with belief in special creation still common, the zoologists of the past century faced a difficult dilemma: Bory de St. Vincent[10], Haeckel and many others were prepared to recognize twelve or more species of *Homo*. On the other hand, zoologists, such as Lamarck and Cuvier, still supported the idea of a single human species.

Darwin[11] brought an end to many of these difficulties however, and in 1871, though he formally left the choice of taxonomic characters open, he was in no doubt that all races of men were quite recently descended from a single primitive stock. Like T. H. Huxley, he always considered man to be a single species, and frequently commented on the physical and temperamental similarities between the races. But he considered the definition of the term species to be a matter of opinion.

To-day, a species is usually defined as "a group of actually or potentially interbreeding natural populations reproductively isolated from other such groups"[12], though some workers in this field still consider the problem of the definition of the species to be academic[13] or inappropriate to taxonomic method[14]. Wherever, among *Homo sapiens*, racial contact has been made, fertile hybrids have resulted. While some groups have no contact with others (for example, Australians have not met Eskimos) this would not invalidate the concept of a 'Rassenkreis'—a polytypic species of world-wide distribution. The extent of man's ecological adaptation and geographical distribution is, apart from his parasites, unique.

Choice of Taxonomic Characters for the Sub-division of *Homo sapiens*

Since Darwin's book was published, anthropologists have recognized the desirability of producing a phyletic classification of modern man, based on studies of comparative anatomy as well as a purely descriptive one. Many obvious racial characters, such as hair form, were first thought to be non-adaptive, and therefore stable. It is now considered that not only does *Homo sapiens* as a whole confirm Bergmann's, Allen's and Gloger's rules, but also that many other characters, not obviously adaptive, are likely to be so. As they became increasingly critical in their approach, anthropologists were concerned to assess the influence of nature and nurture without the possibility of controlled experiment. Evidence of the plasticity of the phenotype had to be derived from studies of monozygotic twins reared apart, and migrant populations. In spite of the amount of detailed work of this kind carried out[15], Harrison has written recently[16] that the prospect of anthropometric techniques based on the phenotype being confidently used for the solution of historical problems remains bleak.

The discovery of the ABO and other blood groups and the pioneering work of the Hirszfields in 1919 led anthropologists to suppose that they had here a tool with which they could produce a true phyletic classification of mankind. This supposition was based on the belief that this was an instance of neutral polymorphism, that blood groups were non-adaptive characters and therefore environmentally and historically stable. They are furthermore related in a simple and direct way to the genotype, and direct taxonomic access to genes avoided the problems of the plasticity of the phenotype. But since Fisher[17] showed that neutral polymorphism was an improbable condition, the hypothesis of the existence of such polymorphism has had to be slowly relinquished. Designation of a character as non-adaptive is often merely a cover for our ignorance. There now exists evidence of statistical correlation between the human blood groups on one hand, and fertility, fœtal disorders, certain kinds of ulcers and other illnesses, on the other[18]. Blood groups are adaptive, and they may well be historically less stable than polygenic characters such as skin colour, hair form, etc., on which the early anthropologists depended. The constant survival of the disadvantageous rhesus-negative gene can only be accounted for by the hypothesis of balanced polymorphism. We must conclude that phenotypic changes may quite rapidly arise both from the direct effect of a change in the environment, and as a result of interaction of the environment with a polymorphic gene[19], apart from the long-term and normal effects of selection on the pool of genetic variation in a population.

The state of our understanding of human variability is at present very fluid, and the data are rapidly accumulating. Workers are at present primarily interested in the geographical distribution of variation and the reason for it. Since it is not known which characters are of more or less value in human taxonomy, we are obliged to aim at a phenetic (or Adansonian) classification, and consider them all: a conclusion which will not intimidate palæontologists handling three or four geometrical variables of mollusc shells, but to a human palæontologist let alone a neotaxonomist, such a conclusion is not attractive. Nor is it known how to evaluate continuous anatomical against discontinuous biochemical characters. It is necessary, therefore, to follow the subjective opinions of experts, and to treat race as a purely contemporary phenomenon, with no regard to its phylogeny. History and archæology must be relied on to supply most of the required information about the origin of the present distribution of mankind.

Table 1 lists some of the most important characters which are at present being recorded in anthropological investigation divided into two groups: (*a*) Polygenic and continuously variable; (*b*) monogenic and discontinuously variable.

Table 1. CHARACTERS OF LIVING MAN INVESTIGATED IN ANTHROPOLOGICAL RESEARCH

Polygenic and continuous	Monogenic and discontinuous
Morphology of soft parts	Blood groups (11 systems)
Body proportions	Hæmoglobins
Stature	Haptoglobins and transferrins
Head and facial measurements	PTC tasting
Fat deposition	Colour blindness
Hair form, distribution and balding	Gross and lethal abnormalities
Tooth size, shape, eruption	Hereditary diseases and disorders
Skin colour, tanning capacity	
Eye colour	
Growth-rate	

Behaviour and Culture

The existence of culture complicates further the investigation of racial differences. In other groups behavioural characters are being given taxonomic consideration[20], and since the definition of a species is behavioural, it may be asked whether behaviour would not be of special importance to studies of *Homo*. The answer at present appears to be that human behaviour, since it is not instinctive, and is closely bound up with human culture, cannot be treated as a taxonomic character of living man. Whether culture, which is an extension of man's body among other things, should receive consideration in this context seems improbable since a strictly scientific investigation of such a character would be impossible, as it would be carried out by culture itself. Tool-making and fire-making may appear at first sight to be exceptions to this, since their existence can be objectively determined, but Oakley[21] has pointed out that early Hominids are likely to have been good imitators, with the result that cultural advances would spread very rapidly among them. In view of this it does not appear that these characters could ever be used to give precise taxonomic distinctions.

Living Sub-species of Man

The deme or local population is the basic unit of study in taxonomy, and, as the data from populations involves statistical treatment for its analysis, only statistical analysis can deliver fully objective results in taxonomy.

Some statistical work has been done at the level of local populations[22]; but in general no progress in this field can be made until agreement on the selection of taxonomic characters is arrived at from the mass of anatomical and biochemical data at our disposal. At the same time, these data of human variability are still too incomplete to achieve an analysis of man as a species, which will offer us objective sub-specific categories. The methods of statistical analysis which might prove suitable for this purpose are discussed in the second part of this article.

The existing classifications of living man, therefore, are based on a very limited number of characters, subjectively selected and assessed. Bernier[23] was the first man to produce a description of the different "species or races" of men. Linnæus listed the four main geographical groups in 1740 (*Systema Naturae*, second edition) and Blumenbach[9] added a fifth in 1775, the Malayans. In the nineteenth century, taxonomic schemes proliferated, from the idea of three races derived from the three sons of Noah, to Bory de St. Vincent's fifteen species, based on hair form[10]. There is, however, to-day a general consensus of opinion both among serologists and morphologists that there are five or six living sub-species of *Homo sapiens*. The terms 'race', 'stock' or 'variety' have been used indiscriminately, however, for the geographical sub-species of man. Anthropologists are often quite unaware of the current significance of these taxonomic terms.

The most generally accepted sub-species of *Homo sapiens* and their valid Latin trinomials are as follows: Caucasians *H. sapiens sapiens* L., 1758; Africans *H. sapiens afer* L., 1758; Asiatics *H. sapiens asiaticus* L., 1758; Amerindians *H. sapiens americanus* L., 1758; Australians *H. sapiens australasicus* Bory de St. Vincent, 1825; Polynesians *H. sapiens neptunianus* Bory de St. Vincent, 1825. (There are more than 130 binomials and trinomials referring to living man which arise through centuries of taxonomic confusion.) Trevor[24] recognizes five sub-species which exclude Amerindians and Polynesians, and include instead the Khoisan people (mainly the Bushmen and Hottentots of South Africa). A good case can be made for the exclusion of the former two rather recently formed sub-species, but it is not considered here that the separation of the Khoisan people from the African sub-species is justified.

These six groups appear to be typical geographical sub-species, each adapted to and living in (originally) a different geographical and climatic zone. Only in the past 400 years has the distribution been upset to the present extent; but it should perhaps be added that although hybrid populations were few and far between until the modern age, the gene flow was probably not fully interrupted at any point, except for short periods. Man is continuously variable, and so-called pure races are a figment of the imagination.

The two main discontinuities at the Bering Straits and the Torres Straits are comparatively recent. The American Indians arrived in America by land about 20,000 years ago and were cut off about 10,000 years ago: the Australians arrived by sea about 10,000 years ago, and so have never been entirely separated from other men. The islanders of South East Asia and the Pacific are for the most part inveterate navigators.

The hybrid populations which have grown up all over the world in modern times serve to emphasize the genetic compatibility of mankind.

Categories Below the Sub-species

Political capital has been made out of the idea of race, and in particular the idea of pure and superior races. Let it be said that no races are 'pure', nor are any known to be superior: it has not proved possible to devise intelligence tests equally applicable to people of different cultures.

Unless the term 'race' is discarded altogether, it must be used with reference to the next taxonomic category below the sub-species. Dobzhansky[15] defines races as "populations differing in the incidence of certain genes but actually exchanging or potentially able to exchange genes across whatever boundaries separate them". Such boundaries in the case of man are usually spatial and cultural. Races are in no sense static, and new races are to-day in process of formation as a result of hybridization (for example, in Hawaii, North and South America). Many classifications of human races have been drawn up, and estimates of the number of 'races' of man in the literature vary from four (when the authors used the term in place of the term 'sub-species') to more than 200. Coon *et al.*[16] recognized 30 races in a recent book; but this classification was somewhat over-simplified. Trevor[14] presents, perhaps, a more realistic account of this complex matter.

At present, therefore, although data of human variability are rapidly accumulating, and understanding of the interaction between man and his environment is increasing, there is no method of assessing the taxonomic value of the data. There does not exist a classification of living man which is objective, and likely to satisfy everyone. A certain amount of agreement, however, has been reached on the main geographical sub-species of living man, and some of the most distinct racial groups. The systematics of this variable and most investigated of animals presents problems which are at present unique to taxonomy.

Fossil Man

The first difficulty to be encountered in the taxonomy of palæontological material is, of course, the inadequacy of the methodology of taxonomy. While the reality of the biological species at any moment in time is clear, palæontological taxa are subjective categories created by the experienced taxonomist. In palæoanthropology the taxonomically 'convenient' gaps are slowly being filled, and while fossil data are still sparse, many of the missing links in the chain of human evolution have been found (Fig. 1). The record is fairly rich in parts but poor in others, and all the finds are incomplete: for example, we have from central and southern Africa five upper Pleistocene crania without mandibles, and from about the same period in north Africa, four mandibles without crania. Whether these fragments represent the same sub-species cannot be determined.

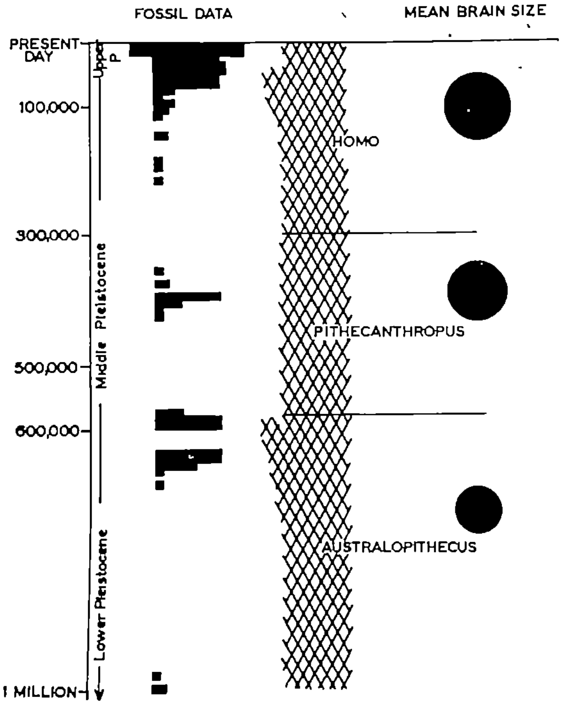

Fig. 1. The past million years of Hominid evolution, showing on the left the extent of fossil data of the three genera. (One small square represents one fragmentary skull, or approximate equivalent.) The central column shows the two points at which fossil evidence indicates that speciation may have occurred. The right-hand column represents the estimated mean brain size of the three genera. The Lower Pleistocene is now recognized to stretch back to between two and three million years; one further fossil has been obtained from this earlier period. The fossil data from recent times is greater than indicated

The difficulty of being objective in this branch of zoology has already been stressed. Each discovery is attended with so much publicity for the discoverer that he frequently become emotionally involved with the precious fossils and is unable to evaluate them in a rational manner. It is for this reason among others that the aim of palæo-anthropologists to-day is to develop an objective methodology in taxonomic work. Therefore, some account of methods of quantitative taxonomy follows, but first there are two more problems to be considered.

The first is the problem of samples. When we consider statistical populations we need to know the mean and variance of the population, and this can be evaluated from a sample of appropriate size. In many branches of palæontology samples of an appropriate size are available but not among the Hominidae. Two assumptions are therefore made: first, that the sample (which may be a single specimen) which we have is representative of the population being studied, and there are reasons for supposing that this may not strictly be the case; secondly, that the variance of the population being studied is similar to that of a modern population of the same kind. These are two rather gross approximations; but they are necessary if we are to extract any statistical information at all from our data, and, of course, they are subconsciously made by any taxonomist making a subjective evaluation from such data. Clearly, the amount of error introduced will be more serious in fine taxonomic distinctions, and much less so in assessing groups of higher taxonomic category.

Whether a number of skulls from a locality belong to one or more populations must be determined in the first place by the archæologist (cf. Brothwell[27]).

Lastly, character selection is of course another sampling problem which applies equally to the experienced taxonomist making subjective assessment of affinity and to the quantitative taxonomist. The difficulty of handling simultaneously the discontinuous and continuous characters of living man has been mentioned, and this problem fortunately does not at present arise in a consideration of fossils, though some blood-group data are now being obtained from the more recent skeletal remains.

It is necessary, however, to face squarely the problem of correlation between characters, since we are dealing with one organ, the skeleton. At the same time the choice of characters is limited, both by the nature of the material and its extent, so that their selection and treatment is of critical importance. It is my opinion that characters should be negatively weighted for both mathematical and functional correlation, and the method to be employed to achieve this is discussed later. If, on the other hand, correlated characters are treated as independent or omitted altogether, distorted results will be obtained from a comparison. Like the experienced taxonomist, we must consider them all, but in relation to each other.

Methods of Quantitative Analysis

The quantitative techniques which have been used in the evaluation of affinity in Hominid taxonomy will now be discussed. Not only is this approach essential to the future development of taxonomy, but anthropologists have been among the leaders in this field, and it is here perhaps that they can best make a contribution to the methodology of taxonomy.

I would first like to mention very briefly the technique of pattern analysis[18]. This is a not uncommon method of handling and comparing taxonomic data, and has been used in many branches of taxonomy. The technique is a quantitative aid to the assessment of affinity, and as it does help us to arrive at a more objective evaluation of the data, its use should be extended and developed.

The more precise techniques fall into two main groups: (1) discriminant functions; (2) measurements of morphological 'distance'.

A discriminant function is designed to determine on the basis of many characters which of two or more taxa a specimen or group belongs to. Proposed by Fisher[29], this multivariate function was used by Bronowski and Long[30] to determine the status of the South African man-apes (the genus *Australopithecus*) over which controversy had raged for many years, and still does. The question was whether the genus belonged to the Hominidae or the Pongidae. Using four measurements on the milk canines of the three groups, Bronowski and Long showed that the man-apes were much closer to the Hominidae than to the Pongidae, and it was therefore suggested that the genus *Australopithecus* should be placed in the family Hominidae. But this use of the discriminant function is open to criticism. In the first place the function was based and evaluated on four measurements of one tooth only, and critics were quick to point out that other characters would give a different answer. This was demonstrated by Ashton, Healy and Lipton[31], who calculated the position of all the *Australopithecus* fossils *vis-à-vis* the Hominidae and Pongidae for all available teeth using 4–8 measurements on each tooth, and they plotted the position of the fossils on two-dimensional scatter diagrams, one for each tooth. No final conclusions could be drawn from their analysis because the results were equivocal, and were not combined in any way. At the same time, the data only concerned the teeth.

While this paper showed very well the variable taxonomic status of the different teeth, it did not inform us of the taxonomic status of the group under analysis. There is, furthermore, a second criticism which must be levelled at the use of the discriminant function for assessing taxonomic status. The use of this function, in the above instance by Bronowski and Long, and in other similar instances, involves the assumption that the two families Pongidae and Hominidae are all-inclusive, and that all new discoveries must belong to one or the other. It did not allow the possibility that *Australopithecus* belonged to a new family, the Australopithecidae, a view which has been held by some anatomists. These two criticisms alone make the discriminant function a very difficult tool to apply. It is potentially most useful when the classification of the specimen is equivocal, and it is precisely in instances of this sort that the new specimen might represent a new taxon. Fisher recommended the use of the function for determining the sex of individuals, and it is indeed ideally suited to this problem, since the two alternatives are inclusive, and the means and variances of the two populations are available—and they are usually not available for problems involving fossils.

The use of two-dimensional scatter diagrams (based on two orthogonal canonical variates) which Ashton *et al.*[31] initiated does seem to be a very useful tool to the taxonomist, and has been utilized more recently by Blackith[32] on insects, and by Jolicoeur[33] to demonstrate the regional variation in the wolf using twelve skull dimensions. With the increasing use of electronic computers complex functions of this kind may be utilized for particular taxonomic problems where the necessary data and facilities are available. Something different is needed, however, from a function of discrimination, in order to facilitate the exact evaluation of taxonomic status. Such functions exist and can be divided into three groups: (*a*) coefficients of similarity; (*b*) simple 'distance' measurements; (*c*) generalized 'distance' measurements.

(*a*) Sneath[34], in his studies of bacteria, developed a simple coefficiency of similarity between taxa that was based on 105 characters (in this example) which either occur in two states (that is, present/absent, plus/minus) or can be treated as such. Sneath has estimated the affinity between his different strains of bacteria by calculating the extent to which different characters in each group occur together. Clearly, if two groups have a lot of characters in common they are likely to be more closely related than two groups with few characters in common. Treatment of continuously variable characters by this method is, however, mathematically unsound and subjective and the method as it stands cannot be satisfactorily applied to Metazoans. Another example of the calculation of the correlation of characters between species has been published by Mitchener and Sokal[35], who recorded 122 characters of 92 species of Megachilid bees, and its taxonomic value appears to be considerable, in spite of a number of criticisms which have been made. (See also Rogers and Tanimoto[36].)

In a modified form this technique might be applicable to living man when enough data are available which can be used for this type of analysis, but will be of little value in evaluating fossil relationships as most of the characters that we have at our disposal (and the exceptions are very few) concern one organ, the skeleton, and are either mathematically or functionally correlated, or most frequently both. The technique does not take into account the varied origin of this correlation and it depends on the data from a very large number of characters to give anything approaching a true picture of affinity. The central problem of taxonomy, moreover, has not been overcome, for the results are still subjective, both as a result of character selection, character coding (that is, continuous characters treated as discontinuous) and character correlation[36].

(*b*) Simple 'distance' measurements or functions of morphological difference have been in use for many years, and were developed by Heinke[37], Pearson[38], Zarapkin[39], Morant[40], and more recently by Penrose[41], Cain and Harrison[42] and Sokal[43]. Like the techniques already mentioned, none of these procedures, with the exception of Penrose's, allows for mathematical or functional correlation between characters, and so will give distorted results when used to analyse the characteristics of a single organ (the skeleton) even though it may reflect a great many other organs. Only Penrose, among them, has introduced a correction factor based on the mean correlation coefficient between every pair of characters (Table 2). The remainder can be of value in comparing the divergence between living taxa, but none of them takes the problem of taxonomic affinity right out of the sphere of subjective assessment, and almost all versions contain fundamental mathematical objections which seriously limit their value. For example, the most recent method proposed by Sokal[43] does not take into account intra-group variation, and the significance of inter-group difference cannot be fully assessed without relating it to the variance within each group. Cain and Harrison[42], on the other hand, handle intra-group variation by considering the "maximum and minimum likely values" of each character, and are thus able to produce a maximum and minimum measurement for the distance between groups. This method has been used recently by Sneath[44]. The formulæ of these various functions, which are very similar, are listed in Table 2.

Table 2. FORMULÆ OF SOME SIMPLE 'DISTANCE' COEFFICIENTS

Pearson (ref. 38): $C.R.L. = \Sigma_1^m d^2/m =$ Heinke's coefficient (1898).

Penrose (ref. 41): $C^2 = \dfrac{\Sigma_1^m d^2 - R[\Sigma_1^m (d)]^2/(1 - R + Rm)}{1 - R}$

Cain and Harrison (ref. 42): $M.C.D. = \Sigma_1^m \delta/m$

Sokal (ref. 43): $C^2 = \Sigma_1^m \delta^2/m$

m, No. of characters; d, difference between the mean values of a character in two populations expressed in units of the standard deviation of one of those populations; R, mean correlation coefficient between characters; δ, difference between the mean values in any two populations expressed as a function of the variability of the character among the different populations.

(*c*) The generalized distance statistic (D^2) was introduced by Mahalanobis[45]. This multivariate function, closely related to the discriminant function already mentioned, will analyse the relationship between continuous characters, discounting both the mathematical and functional correlation between them, and it will produce a true function of morphological distance on the basis of characters which can be quantified between the groups under consideration. Like all these measures, it does assume a common dispersion matrix in the different populations—an assumption which in the circumstances is likely to be justified (that is, normal distribution, similar variance, etc.). A very similar function, A^2, has been introduced by Defrise-Gussenhoven[46].

A further great advantage of a technique based on multivariate analysis is that after a certain point the addition of further data does not affect the accuracy of the result and, therefore, so long as sufficient characters are used, the subjective element involved in their choice is lost. Under proper conditions, therefore, this technique is an answer to many of our problems: its great disadvantage is that it involves a tremendous amount of computation, but with electronic computers, this is no longer of overriding importance. Owing to the complexity of D^2 it has not been used as much as it should be, nor has it yet been adapted for the analysis of discontinuous variation, though this should not present insuperable problems. Examples of the use of this function include Trevor[47], Jones and Mulhall[48], Mahalanobis *et al.*[22], Mukherjee *et al.*[49], Blackith[32,50,51] and Giles[52].

While there is certainly room for improvement and development of techniques of this kind, it would appear that an approach along these lines is the most valuable that exists to elucidate the taxonomic relationships of evolving organisms. Blackith[53] has recently reviewed the broad field to which multivariate techniques can be applied, and Jahn[54] has gone so far as to suggest that the future of taxonomy lies in the use of electronic computers.

From Affinity to Phylogeny

Having reached an assessment of phenetic affinity between fossils, the geographical, geological, and palæontological context in which they were found will give much of the information needed to assess their phyletic relationships. New dating methods appear to give us remarkably accurate data about the relative and absolute age of different fossils[55]. Where a fossil record exists direct evidence can give information about phyletic relationships which can only with difficulty be obtained from living forms[56]. It is recognized that estimates of phenetic affinity between contemporary groups will mask the existence of convergent evolution, but while this may be an important consideration in the systematics of macro-evolution, it does not appear to be a problem involved in Hominid taxonomy, since the evidence at present strongly suggests a monophyletic descent without much speciation. Convergence on a micro-scale within a species lineage is not a factor which can seriously affect our taxonomic conclusions.

In considering the process of Hominid evolution, Mayr[57] and Dobzhansky[25] have both expressed the opinion that speciation has not occurred since the Hominidae branched from the Anthropoid stock: that man has evolved as a single species throughout the period with which we are concerned. On the principle of Occam's razor, it is right not to postulate a plurality of vertical taxonomic divisions without evidence of them. However, at least one occasion when speciation has occurred can now be recognized.

Australopithecus robustus and *Pithecanthropus erectus* both existed, according to the latest estimates based on potassium argon dating methods, at about 0·6 million years B.P. (at Swartkrans and Djetis). Being allopatric, their biological status is uncertain, but on morphological grounds they are certainly specifically distinct. Furthermore, evidence suggests that the two species of *Australopithecus* (*A. africanus*

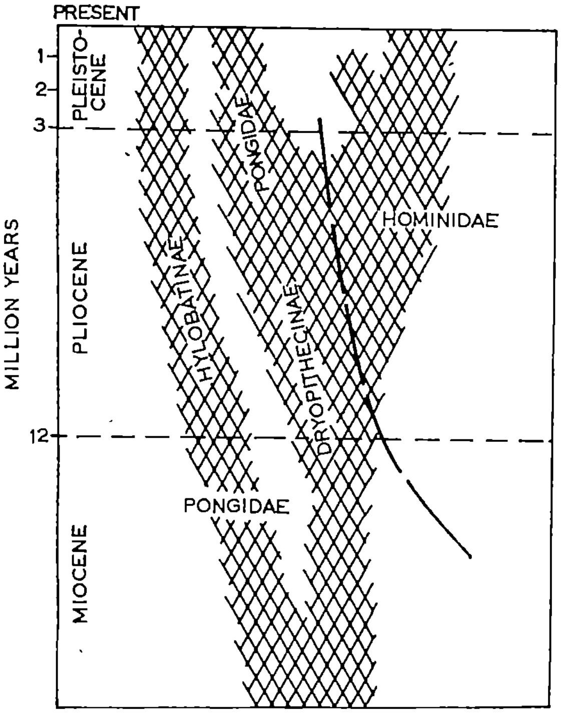

Fig. 2. An imaginative diagrammatic representation of the evolution of the Hominoidea, showing the two families, the Pongidae and Hominidae

and *A. robustus*) are not so much successive forms, but two contemporary and discontinuous groups, since they both appear to have existed over a long period in eastern and southern Africa (1·3–0·6 million years)[21]. *A. africanus* would therefore be likely to be near the lineage leading to *Pithecanthropus*, while *A. robustus*, a coarser and more ape-like form, is probably a side branch which became extinct after the *Pithecanthropus* stage had been reached in Java.

There is one other point at which speciation may have occurred where there appear to exist biological criteria to distinguish Neandertal man in western Europe from the contemporary sub-species of *Homo sapiens*. The latter replaced the former in France very suddenly about 40,000 years B.P., without any known morphological continuity except in past time. If intermediate fossil forms are not discovered in the future which retain genetic continuity with the extreme Neandertal forms, we shall have to recognize western European Neandertal man as a distinct biospecies from *Homo sapiens*. It seems preferable for the present, however, to classify this rather aberrant group as a sub-species of *Homo sapiens*. The same remarks apply to the sub-species *Homo sapiens rhodesiensis* and *Homo sapiens soloensis*, which were terminal sub-species in Africa and Asia of the Neandertaloid type of man. In these instances, however, the evidence of genetic discontinuity is less clear and it seems possible that these forms were absorbed by the advancing groups of modern *Homo sapiens*.

The classification which is presented here (Table 3) does not imply that all known fossils can be confidently assigned to one or other of the taxa. Many must remain in a suspense account, and the temptation to systematize with insufficient data must be resisted. In particular, three genera which have been created on the basis of three important fossils are not mentioned. *Telanthropus* from South Africa is perhaps a South African form of *Pithecanthropus*, but the fragments are too few to reach any certain conclusion. *Meganthropus palaeojavanicus* is perhaps a south-east Asian form of *Australopithecus*, but again the evidence is insufficient. The skull named *Zinjanthropus* is probably a member of the genus *Australopithecus*, but full details have not yet been published about this important find. The so-called *Chellean* man from Oldowai is probably a member of the African sub-species of *Pithecanthropus*, *P. erectus mauritanicus*.

Table 3

Family:	Hominidae Gray, 1825
Genus:	† *Australopithecus* Dart, 1925
Species	† *A. africanus* Dart, 1925
Subspecies:	† *A. africanus africanus* Dart, 1925
	† *A. africanus transvaalensis* Broom, 1926
	† *A. robustus* Broom, 1938
	† *A. robustus robustus* Broom, 1938
	† *A. robustus crassidens* Broom, 1949

	† *P. erectus* Dubois, 1894
	† *P. erectus erectus* Dubois, 1894
	† *P. erectus pekinensis* Black and Zdansky, 1927
	† *P. erectus mauritanicus* Arambourg, 1954
Genus	*Homo* L. 1758
	H. sapiens L., 1758
	H. sapiens sapiens L., 1758
	H. sapiens afer L., 1758
	H. sapiens asiaticus L., 1758
	H. sapiens americanus L., 1758
	H. sapiens australasicus Bory de St. Vincent, 1825
	H. sapiens neptunianus Bory de St. Vincent, 1825
	† *H. sapiens neanderthalensis* King, 1864
	† *H. sapiens rhodesiensis* Woodward, 1921
	† *H. sapiens soloensis* Oppenoorth, 1932
	† *H. sapiens krapinensis* Gorganovic-Kramberger, 1902

When we come to consider the horizontal taxonomic boundaries which sub-divide the Hominidae in time, the position of them and the rank to be applied to them is of course arbitrary. Mayr[57] would place the whole family in the genus *Homo*, while other workers have recognized ten or more genera. Compared with other mammalian groups it may be considered that the length of time of the existence of a taxon is small, and that too much splitting has occurred. It can be argued, however, that the rate of Hominid evolution was very high, and the different genera show the degree of difference appropriate to that category. The genera here used follow the scheme of Simpson[58]. There is, however, much to be said for sinking the genus *Pithecanthropus* to form the species *Homo erectus*, and many workers are now taking this view. This is the kind of problem which only mutual discussion can resolve.

Future discovery will no doubt make it necessary to create many new taxa, and great difficulty will doubtless arise over the classification of fossils from the Pliocene. If Fig. 2 represents in any sense the kind of situation that may be expected, it is difficult to see how the methodology of taxonomy as it stands at present can effectively handle a situation such as this may prove to be. So long as taxonomy is a matter of opinion it will remain a matter of controversy.

A CHILDREN'S CANCER DEPENDENT ON CLIMATIC FACTORS

By DR. DENIS BURKITT

Department of Surgery, Makerere University College Medical School and Mulago Hospital, Kampala, Uganda

THE incidence of many cancers varies enormously in different races. Notable examples are bowel carcinoma, so common in European races and so rare in the Bantu, and primary liver carcinoma with the reverse relationship. These and other tumours probably owe their differing racial incidence more to environmental than to genetic factors, as negroes in America show a tumour pattern approximating much closer to the white population there than to the pattern observed in Africa[1].

Until recently no cancer has, to my knowledge, been shown to occur only in certain clearly defined geographical locations, and within these boundaries to affect different tribes and races without discrimination.

Five years ago a number of hitherto unconnected tumours affecting children were recognized as being but different manifestations of a single tumour syndrome[2]. At about the same time it became evident that this tumour was very prevalent in certain parts of Africa while it was quite unknown in other parts[2].

The tumour has been histologically identified as a malignant lymphoma[3,4], but the condition is recognized rather as a clinical syndrome than as a specific tumour. Malignant lymphomata, presenting usually with generalized lymph-node enlargement, occur throughout the world. The unusual anatomical distribution of this tumour syndrome[2,4–7] is apparently unique, and with one exception, which will be referred to later, is confined to certain areas of tropical and sub-tropical Africa.

The age incidence differs from that observed in any other tumour. Nearly all cases recorded have occurred between the ages of 2 and 14 years, with a peak incidence at 5 years. The incidence appears to be approximately the same in both sexes[2,5].

This tumour syndrome accounts for more than 50 per cent of all children's cancers seen in Uganda[2,7]. More than 200 cases have been recorded during the last eight years.

This tumour appears to traverse all barriers of race and tribe. Although unknown in India, it has been observed in Indian children domiciled in Africa in the proportion expected from the relative population figures[5].

The clinical characteristics have already been reported[2,5–7]. The distribution of tumour deposits throughout the body is totally unlike that observed in any other tumour. Moreover, the virtually simultaneous development of multiple tumours in sites where tumours were hitherto least expected to occur presents a strikingly characteristic clinical picture. Although there is a remarkably constant pattern of distribution, the presenting features vary, and are dependent on the particular lesion most in evidence at the time.

The most characteristic feature of this syndrome is the remarkable tendency for tumours to grow in

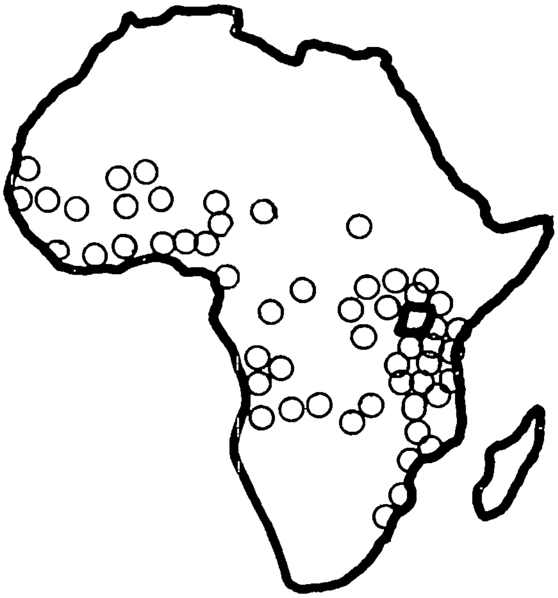

Fig. 1. Map of Africa showing the known distribution of the tumour syndrome. Each circle represents an area where this tumour has been recognized

Reproduced by kind permission of the Annals of the Royal College of Surgeons of England

the jaws. In more than 140 of the cases recorded in Uganda, tumours were present in the jaws, and in a high proportion of these more than one quadrant, and in 16 cases all four quadrants were involved. The tumours grow rapidly and cause gross disfigurement. The maxillary tumours commonly invade the orbit, presenting as an exophthalmos and eventually destroying the eye. These lesions have frequently been mistaken for retinoblastomata.

Other striking features are the bilateral ovarian tumours, present in more than 70 per cent of female patients who have been submitted to laparotomy or come to autopsy, the bilateral thyroid tumours and the very high incidence of multiple renal tumours, which are also usually bilateral. The adrenals, heart and stomach are frequently involved, and lesions in the spinal canal make this tumour the commonest cause of paraplegia in children in the areas where the syndrome occurs.

Although tumours have been observed in many of the long bones, these lesions are relatively rare compared with the jaw tumours. Despite the fact that a more or less generalized enlargement of the lymphatic glands and spleen is the most prominent feature of malignant lymphoma as generally understood, clinical enlargement of these structures is exceptional in this syndrome. This unusual pattern and the rarity of pulmonary involvement constitute some of the most characteristic and unusual features. Untreated, the tumours grow exceedingly rapidly and terminate fatally, usually within six months.

Epidemiological aspects have also been discussed[2,5–8]. In view of the fact that the characteristic jaw tumours cannot easily be mistaken for any other condition these have been used to determine the geographical distribution of the tumour syndrome.

After wide distribution of illustrated leaflets accompanied by a questionnaire it became obvious that the tumour syndrome occurred right across tropical Africa from the coast of East Africa to Dakar in the extreme west (Fig. 1). In West and Central Africa the northern limit of the tumour belt is about 15° latitude; but this line falls below 10° in the east. Populations fall off, in many instances to virtual desert, along this line so tumour incidence naturally tends to disappear. The condition is common in West Africa as far south as the sea coast and has been recognized as far south as the middle of Angola.

A much more detailed study, including a 10,000-mile roads safari, has been undertaken in East and Central Africa. Geographical plotting of all cases observed in Uganda showed that the only factor, other than population, affecting tumour distribution was altitude. Near the equator the tumour does not appear to exist above an altitude of about 5,000 ft.

East and Central Africa with its varying contours produced mountain ranges and the two limbs of the Great Rift Valley were examined in some detail to determine the areas of tumour distribution. The findings of this survey can be summarized as follows: (1) Throughout Uganda, Kenya and Tanganyika the tumour can occur anywhere except at altitudes of more than about 5,000 ft. with the possible exception of the southern part of Tanganyika. (2) The off-shore islands of Zanzibar and Pemba are a notable and significant exception. No case of this syndrome has been observed in these islands with a population of more than a quarter of a million. (3) Throughout the Federation of Nyasaland and Southern and Northern Rhodesia, the syndrome is found only in or near the great river valleys, and on the shores of Lake Nyasa. (4) It is common throughout the coastal plain of Mozambique. (5) It is virtually unknown in South Africa. (6) This pattern of distribution does not coincide with population densities.

It is thus evident that the critical altitude above which the tumour is not observed falls progressively as the distance from the equator increases. Altitude is therefore only a limiting factor in so far as it reflects temperature. The actual limiting factor would appear to be a minimum temperature of about 60° F. in the coldest season of the year (July) (Fig. 2).

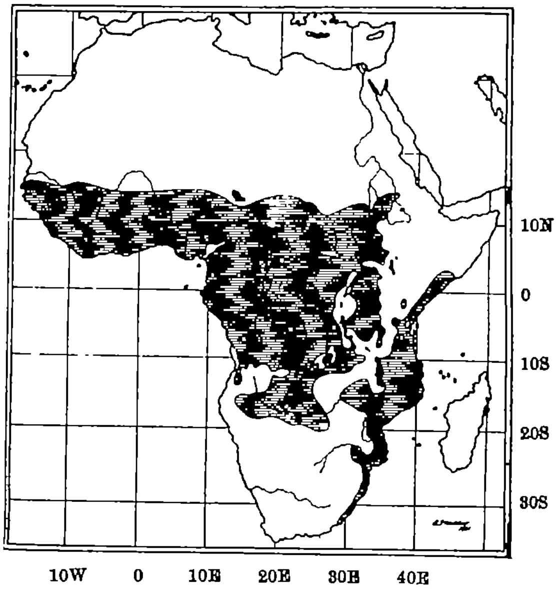

Fig. 2. Map of Africa from which have been eliminated (1) all areas where the temperature falls below 60° F., and (2) areas where the rainfall is below 20 in. a year

Reproduced by kind permission of the Annals of the Royal College of Surgeons of England

There is no evidence that this tumour occurs in any country outside Africa with the exception of a few cases reported from New Guinea (Ten Saldam, personal communication, 1960).

The fact that the tumour distribution is dependent on climatic factors strongly suggests that some vector, perhaps a mosquito, is responsible for its transmission. This would naturally suggest that some virus may be the responsible agent.

No human tumour has yet been shown to be virus-induced but a number of virologists are now investigating the virological aspects of this tumour syndrome.

It was Prof. J. N. P. Davies who first suggested to me the possibility that this tumour might be virus induced. Dr. A. J. Haddow, director of the Virus Research Institute at Entebbe, has greatly assisted me in correlating tumour distribution to climatic factors.

I thank the Chief Medical Officer, Ministry of Health, Entebbe, for permission to publish this article.

THE CROSS-CHANNEL ELECTRIC POWER LINK

THE linking by an undersea cable of the electric power networks of France and England, inaugurated officially on December 8, 1961, by the Minister of Power, the Right Hon. Richard Wood in England and the Minister for Industry, Jean Marcel Jeanneney in France, is an event of both technical and economic significance*.

The cable connexion lies across the channel from Le Portel, a suburb of Boulogne, to Lydd in Kent. By means of this link either country will be able to receive from the other up to 160,000 kW. of electrical power. The interchange of power between the two countries is rendered advantageous by the difference, between France and England, in the time of occurrence of the peak demand for electric power. It is estimated that the scheme will result in a saving of capital expenditure of about £8,000,000 in generating equipment and an annual saving in operating costs of £300,000. The total cost of the project has been some £5,000,000.

The power networks of Britain and of western Europe are alternating current systems operating at a frequency of 50 c./sec. The link joining the two systems uses direct current. Notwithstanding the fact that the use of direct current involves elaborate rectifier-inverter equipment at each cable terminal, this system has over-riding advantages. In the first place the transmission of electric power by alternating current in underground or submarine cables becomes difficult if long distances are involved, by reason of the large charging current drawn by the electrostatic capacitance of the cable. This difficulty is, of course, absent with direct current and in addition, for a given voltage, the cable for direct current is more economical of insulation. Secondly, two linked alternating-current systems must run in synchronism. Between alternating-current generators running in parallel there is an automatic synchronizing action, but this is associated with a flow of reactive current and, in consequence, the phenomena of load sharing are not simple. The problems of maintaining synchronism between the British and Continental systems would have been very great, none the less the initial plans for a cable link were drawn up on the basis of alternating current. Linkage by direct current leaves the two systems entirely free so far as small variations of frequency are concerned and enables the exchange of power to be made practically independently of internal variations in load or the occurrence of faults within either system.

An experimental high-voltage direct-current transmission system was undergoing development in Germany during the Second World War. After the War similar experiments in very-long-distance transmission were initiated in the U.S.S.R. It was, however, in Sweden that pioneer work was done which resulted in the first commercial installation. In 1943, Dr. Uno Lamm of the A.S.E.A. Electrical Co. in Sweden, assisted by a small team of research and development engineers, started work on the difficult problem of designing the heavy-current high-voltage mercury-arc rectifier valves required for such systems. Full-scale experiments and prolonged tests were involved. As a result of this a system was designed and built to supply 20 MW. to the island of Gotland in the Baltic by means of a single submarine cable carrying current at 100 kV. d.c. and utilizing a sea and earth return. The successful operation of this scheme engendered confidence in the utilization of direct current for the cross-Channel link.

Transmission is effected by two cables about 34 miles long operated with a potential difference of 200,000 V. The system is symmetrical with respect to earth so that the two conductors are 100,000 V. negative and positive to earth respectively.

On the English side power is drawn from the 275 kV. grid and on the French from the 225 kV. system. Each sub-station comprises transformers, a.c. switching equipment, control equipment and rectifiers. Rectification or inversion is effected at each end by two groups, connected in series, of six grid-controlled mercury arc rectifiers together with by-pass valves. The control of power flow is effected by impulses applied to the control grids of the valves. Normally, reversal of power flow is effected by the automatic operation of polarity reversing switches. Elaborate precautions have been taken to avoid the transmission of harmonic voltages into the a.c. system and to suppress the effects of high-frequency ripple in the d.c. system. Control engineers communicate directly with one another and with sub-station attendants over rented Post Office lines. Once the load and direction of power flow have been set, operation is entirely automatic and does not require the maintenance of a communication link between the two ends.

Apart from the economic advantages which the scheme offers, it will provide a most valuable opportunity for the acquisition of operating experience with a system which will find application in other parts of the world.

---

* *Cross-Channel Power Link*. By J. H. M. Sykes. (Central Electricity Generating Board, Winsley Street, London, W.1, December 1961.)

Equipment is already being manufactured for a scheme linking the north and south islands of New Zealand across the Cook Strait. This cable will transmit 600 MW. at 500 kV.

Operation of the cross-Channel system was temporarily suspended as a result of damage to one of the cables about four miles from the English coast by a ship's anchor on January 12. It has been reinstated for the time being at half-power, utilizing the damaged cable as an earthed return conductor. J. Greig

OBITUARIES

Dr. Ezer Griffiths, O.B.E., F.R.S.

Dr Ezer Griffiths died at Teddington on February 14. His intellectual qualities combined with his open-hearted friendliness to win him the respect and affection of any community to which he belonged. His own interests and affections were deeply bound up with the National Physical Laboratory, which he served for nearly forty years.

Griffiths went to work at the National Physical Laboratory in 1915 being then twenty-seven years old and having already gained considerable experience as a research worker on thermal properties. A native of Aberdare, he had graduated at University College, Cardiff, with first-class honours in physics, gained the Isaac Roberts research scholarship and later elected a fellow of the University of Wales. With Principal E. H. Griffiths, he determined the heat capacities of several metals down to liquid air temperatures and also published papers on related subjects.

Early in 1916, full responsibility for the work of the Heat Section at the National Physical Laboratory fell on Griffiths and remained with him until his retirement in November 1953. Work on thermal insulation had already been started and was to assume major proportions, leading to the two outstanding investigations made by Griffiths in the 1920's into the transport to Great Britain of apples from Australia and frozen lamb from New Zealand. A series of special reports on this work was published in the years 1924–33 by the Food Investigation Board and can still be read with considerable profit. This was the work of which Griffiths himself was most proud and which he loved to recall in later years.

During the 1920's and 1930's Griffiths was also actively engaged on investigations for the Building Research Board and the Electrical Research Association. As a result of these researches, he published papers on heat transmission through walls, concretes and plasters. and on the thermal resistivity of solid dielectrics. Knowledge of the thermal resistivity of these component materials had been required in connexion with the calculation of the loss of heat from electrical machinery. For the Alloy Steels Research Committee he determined thermal expansion, total heat and thermal and electrical conductivity for twenty-one commercial steels over a wide temperature-range. This information was required in connexion with the heating and cooling of steel ingots.

Other subjects on which Dr. Griffiths worked were the use of the spectral line reversal method for the measurement of flame temperatures (1928 and 1929), the dependence of the mobility of ions in air or relative humidity (1929), the heats of combustion of carbon monoxide in oxygen and of nitrous oxide in carbon monoxide at constant pressure (1933), and the specific heat of pure iron to about 950° C. (1940).

During the Second World War, Dr. Griffiths and his Section were engaged on many special problems. These included tests on war emergency cold stores, in which the usual cork insulation had been replaced by slag wool filling in a cavity-wall construction; storage and transport of meat in the tropics, heat treatment of stored grain to guard against pest infestation; tests on tanks and on special military equipment under simulated tropical conditions; temperature measurements of jet propulsion turbine blades—these were undertaken during the initial development work on the jet engine—problems of flax drying and processing, measurement of humidity and temperature at high altitudes, measurement of gun-barrel temperatures in connexion with the problem of gun erosion and measurement of the distribution of temperature at various distances in the flame of large flame projectors.

Griffiths was elected a Fellow of the Royal Society in 1926. He received the Moulton Medal of the Institution of Chemical Engineers in 1935 for a joint paper (with R. W. Powell) on the fundamentals of evaporation. In 1950, he was awarded the O.B.E.

The refrigeration industry recognized their great debt to him and constantly sought his advice. He was elected president of the Institute of Refrigeration from 1936 until 1938, later serving as a member of the Council, and was chairman of the Research Committee at the time of his death. He was well known internationally as an authority on refrigeration, being president of the Institut International du Froid during 1951–59, and after that president d'honneur. He was elected president of the Institute of Engineers in Charge in 1961. Many other organizations benefited from his knowledge and willingness to serve the public good. He was a governor of the National College for Heating, Ventilating, Refrigeration and Fan Engineering, and at various times held office or served on committees of the Physical Society, the British Association, the International Union of Pure and Applied Physics and the Twickenham Education Committee.

G. B. B. M. Sutherland

Prof. Władysław Dziewulski

Władysław Dziewulski was born in Warsaw on September 2, 1878. He entered the University of Warsaw and graduated in 1901. This was followed by one year of study in the University of Gottingen (1902–3). In 1903 he went to the Astronomical Observatory of the University of Cracow as an assistant. In 1906 he was awarded the Ph.D. degree of that University for his work on the secular perturbations of Eros caused by Mars. In 1907 he went to Göttingen again for two years of study and worked, under Karl Schwarzschild's direction, on photographic photometry of stars. In 1909 he was appointed adjunct at the Cracow Observatory, and in 1916 became lecturer in astronomy in the University of Cracow. In 1919, Dziewulski was appointed professor of astronomy in the University of Wilno. There he organized the Astronomical Observatory and remained its director until December 1939, when the Polish University of Wilno was closed. He was elected rector of the University of Wilno in the year 1924–25.

The Astronomical Observatory of the University of Wilno, founded by Władysław Dziewulski, was destined mainly for astrophysical research. Dziewulski observed the Cepheid Variables visually and photographically. Beside the observations of variable stars, Władysław Dziewulski's astronomical researches were devoted to problems of statistical investigations of stellar space motions in the local system of the Galaxy. His contributions concerned the peculiar motions of stars of different spectral and luminosity classes, the moving clusters and the local rotation of the stars of *A* type. During 1922–26 his interests were directed to the problems of the determination of the solar apex by the Bravais method and of the determination of the vertex from the data of the *Boss Preliminary General Catalogue*. In 1945 Dziewulski went to Toruń, where the new University was founded. He took an active part in its organization and together with Prof. W. Iwanowska founded the Astronomical Observatory of the University of Toruń at Piwnice near Toruń. In that Observatory he continued his research on secular perturbations of minor planets, on the space motions of stars and on Cepheid Variables. He took a deep interest in the history of Polish astronomy of the nineteenth century, especially in the history of the Wilno Astronomical Observatory in the eighteenth and nineteenth centuries.

Władysław Dziewulski was a member of the Polish Academy of Sciences and Fellow of the Royal Astronomical Society. He was an excellent teacher and attracted many young pupils to astronomy. He was elected professor emeritus in 1960 but continued his research work until his death.

He died in Toruń on February 6, 1962.

EUGENIUSZ RYBKA

NEWS and VIEWS

The Anti-Locust Research Centre:

Dr. T. H. C. Taylor

DR. T. H. C. TAYLOR retired from the directorship of the Anti-Locust Research Centre, London, on March 31. Dr. Taylor has had a long and varied career in entomology; he graduated with first-class honours at the University of London in 1924 from what was then University College, Reading, and went to Fiji to undertake work on the biological control of the coconut moth which was then causing heavy damage in the plantations. In the course of his work for Fiji he travelled widely in Melanesia, Indonesia and the West Indies looking for suitable parasites. He and his collaborators, J. D. Tothill and R. W. Paine, working with the Government entomologist, H. W. Simmonds, succeeded in completely controlling the moth, and they described this classical example of biological control in a book, *The Coconut Moth in Fiji: a History of its Control by Means of Parasites*. Taylor and Paine went on to establish successful biological control of the coconut leaf-mining beetle and the coconut scale. In 1935 Taylor was transferred to Uganda, where he worked mainly on pests of cotton and coffee and their natural enemies, and during this period he published several papers and was awarded the D.Sc. degree. In 1944 he returned to England to join the Commonwealth Institute of Entomology, where he became assistant director in 1946. In 1953 he transferred to the Anti-Locust Research Centre as deputy director, and in 1959 he succeeded Dr. (now Sir Boris) Uvarov as director.

Dr. Taylor's years of office as director have been marked by enlargement of the scope and functions of the Centre, which has long been regarded as the main international body for locust research; important developments during this time have been the establishment of the Centre as one of the units of the new Department of Technical Co-operation and the increasing part it has played, notably in collaboration with the Food and Agriculture Organization, in promoting international co-operation in locust research and control. The recent constitutional changes in Africa have reacted on overseas locust organizations, and the Centre in general and Dr. Taylor in particular have played a large part in guiding the policy of newly emergent countries in the locust sphere.

Dr. P. T. Haskel

DR. TAYLOR has been succeeded as director by Dr. P. T. Haskell, who has been deputy director of the Centre since 1959. Dr. Haskell graduated at the Imperial College of Science and Technology in 1951 with first-class honours in entomology and was appointed assistant lecturer and then lecturer in entomology in the Department of Zoology. He gained the degree of Ph.D. in 1955 for research in insect acoustics, and in 1956 was awarded the Huxley Gold Medal for Biology for this work. He is most widely known for his work on insect acoustics and behaviour, and his recent book, *Insect Sounds*, is the only general text-book on the subject. Dr. Haskell joined the Anti-Locust Research Centre in 1955 to take charge of physiological research and devoted much time to building up such work in the Centre and also to stimulating physiological work on locusts in university departments at home and abroad. Since his appointment as deputy director he has travelled widely in Africa to familiarize himself with the problems relating to the most important locust species and to discuss and advise on problems of locust research, in which he intends to remain active. By both lecturing and writing he has contributed greatly to the dissemination of knowledge concerning locusts and their control.

Sir Henry Head, F.R.S.

THE centenary of the birth of Sir Henry Head, who achieved considerable distinction in the field of medicine, has been marked by a series of articles in a recent issue of *Brain* (84, Part 4; 1961), which he edited from 1910 until 1925. Sir Henry was born on August 4, 1861, and was educated at Charterhouse and Trinity College, Cambridge. He studied physiology under Hering at Prague and took a medical degree at Cambridge and University College Hospital. He was responsible between 1893 and 1896 for showing the areas of reflex cutaneous hyperæsthesia and hyperalgesia, due to visceral disease, and also the segmental distribution of the sensory nerve roots involved. The man and his ideas are described by

Lord Brain, while Dr. K. W. Cross explains how Head's collaboration with Hering at Prague later led to the discovery of his paradoxical reflex. Head's considerable contribution to our knowledge of sensation is examined by Dr. R. A. Henson, while his theories of aphasia are analysed by Dr. Macdonald Critchley. The symposium also includes a detailed bibliography of Head's original works.

U.K. Atomic Energy Authority

The United Kingdom Atomic Energy Authority has announced the following senior appointments: in the Production Group, Mr. S. F. Hines, formerly general manager, Capenhurst, is appointed production director, with his headquarters at Risley, and Mr. W. R. A. Taylor, formerly deputy general manager, is appointed general manager, Capenhurst, to succeed Mr. Hines; in the Reactor Group, Mr. P. W. Mummery is appointed deputy director, Atomic Energy Establishment, Winfrith. These appointments took effect from April 1.

S. F. Hines, O.B.E.

Mr. Hines was educated at St. Albans School and the University of London. In 1930 he joined the staff of the Royal Gunpowder Factory, Waltham Abbey, and in 1936 transferred to the Royal Ordnance Factory, Irvine. In 1939 he was appointed superintendent of the Factory at Pembrey, and in 1944 became superintendent of the Factory at Drigg, Sellafield and Bootle. In 1946 Mr. Hines was appointed general manager of the Atomic Energy Factory at Springfields and was responsible for starting up this plant for uranium purification and fuel element manufacture. In 1950 Mr. Hines became general manager of the new gaseous diffusion plant at Capenhurst.

W. R. A. Taylor, O.B.E.

Mr. Taylor was educated at Scunthorpe Grammar School and the University of Cambridge. During the War he was a member of the Directorate of Filling Factories, becoming chief technical assistant in 1945. In 1946 he joined the Department of Atomic Energy at Risley and in 1954 was appointed works manager, Springfields Works. In 1956 Mr. Taylor was appointed deputy general manager, Capenhurst Works (gaseous diffusion plant). In July 1956 he was a member of the Duke of Edinburgh's study conference.

P. W. Mummery, O.B.E.

Mr. Mummery was educated at Rotherham Grammar School during 1936–44 and Queen's College, Cambridge, 1944–47. He joined the Authority in August 1947 as a scientific officer at Harwell. On January 1, 1952, he was promoted to senior scientific officer, Atomic Energy Research Establishment, Harwell, in 1955 to principal scientific officer, and in 1957 to senior principal scientist. Mr. Mummery later became head of the Power Reactor Branch, Reactor Division, Harwell, and is at present head of Industrial Power Reactor Division, Atomic Energy Establishment, Winfrith, Dorset.

Reorganization of Radio Standards Laboratory at the U.S. National Bureau of Standards

The Radio Standards Laboratory at the Boulder Laboratories of the National Bureau of Standards, U.S. Department of Commerce, has been divided into a Radio Standards Division and a Circuit Standards Division to provide unified direction for a growing programme. Dr. J. M. Richardson will continue as head of the Radio Standards Laboratory, which is responsible for providing the central basis for the complete, consistent, uniform and accurate measurement of physical quantities pertaining to radio science, and assurance of international co-ordination of such measurements. Dr. Y. Beers, chief of the Radio Physics Division, will direct research concerning the interaction of electromagnetic fields with matter having possible application to radio standards, frequency standards, time scales, atomic and aggregate properties of matter, and constants of physics. The Division will also develop certain national standards and direct the dissemination and international co-ordination of the results. The Circuit Standards Division, headed by Dr. G. E. Schafer, will conduct research and develop national standards of physical quantities pertaining to radio circuits and measurement techniques, disseminate the standards, especially by calibration services, and direct their international co-ordination.

The Iron and Steel Institute

The following changes have been announced by the Council of the Iron and Steel Institute: *Honorary Vice-President*, Mr. D. A. Oliver (director of research, B.S.A. Group of Companies); *Vice-President*, Mr. E. W. Senior (director, British Iron and Steel Federation); *Members of Council*, Dr. N. P. Allen (superintendent, Metallurgy Division, National Physical Laboratory), and Sir Douglas Bruce-Gardner (deputy-chairman, G.K.N. Steel Company, Ltd., and joint managing director, Lysaghts Scunthorpe Works); *Additional Honorary Members of Council*, Mr. A. Jackson (technical adviser on steelmaking, United Steel Companies, Ltd.), and Prof. F. D. Richardson (professor of extraction metallurgy, Imperial College of Science and Technology).

Awards

The Council of the Iron and Steel Institute has made the following awards: *Bessemer Gold Medal for* 1962, Sir Charles Goodeve, director of the British Iron and Steel Research Association, president during 1961–62 of the Institute; *Sir Robert Hadfield Medal for* 1962, Mr. G. T. Harris, assistant managing director, Jessop-Saville, Ltd.; *Williams Prizes*, Mr. H. I. A. Archibald (Stewarts and Lloyds, Ltd.) for the paper "The Application of a Digital Computer to the Pre-operational Problems of Programming the Extraction and Supply of Iron Ore", and Mr. M. C. Harrison and Mr. P. Truscott (Steel Company of Wales, Ltd.) for the paper "Operation of the Oxygen/Steam-blown Converters at the *VLN* Steel Plant of the Steel Company of Wales, Ltd."; *Andrew Carnegie Silver Medal for* 1961, Mr. J. S. White (University of Liverpool) for the papers "Kinetic Features of Upper and Lower Bainite Formation in a Plain Carbon and a 3 per cent Ni-Cr Steel" and "The Effect of Up-quenching on the Kinetics of Bainite Formation".

International Co-operation in Outer Space

The U.S.S.R. has nominated Prof. V. A. Bugaev and the United States has nominated Dr. M. Alaka to be consultants to the Secretary-General of the World Meteorological Organization in studies related to the preparation of a report on global benefits to be derived from meteorological satellite research. These two scientists began work in Geneva on March 13, 1962. This co-operation between the world's two leading countries on research in outer space results from a resolution of the General Assembly of the

United Nations, as well as from the mutual desire of both countries. The resolution of the United Nations recommends the early and comprehensive study in the light of developments in outer space of measures (*a*) to advance the state of atmospheric science and technology so as to provide greater knowledge of basic physical forces affecting climate and the possibility of large-scale weather modification, and (*b*) to develop existing weather forecasting capabilities and to help member States make effective use of such capabilities through regional meteorological centres. It also requests the World Meteorological Organization to submit a report on arrangements to achieve those ends. This report will be studied by member Governments and by the Economic and Social Council prior to further consideration by the General Assembly of the United Nations. It is expected that Dr. H. Wexler, a leading American meteorologist, will shortly join Prof. Bugaev and Dr. Alaka.

Teaching of Science and Mathematics: Nuffield Foundation Programme

THE Nuffield Foundation has set aside £250,000 towards the cost of a comprehensive long-term programme to improve the teaching of science and mathematics in schools. Co-ordination of the whole programme will be undertaken by the director of the Foundation, Dr. Leslie Farrer-Brown, in consultation with the Curriculum Study Group in the Ministry of Education and all branches of the education service, with the professional institutions concerned, and with industry. The five sections chosen as starting points for the programme are: physics, chemistry and biology for 11–15-year-olds in grammar schools and streams; secondary school mathematics; and primary and secondary school science in general. The aim in the first three sections will be to provide a complete range of aids designed by teachers for teachers. The work will be based on the extensive new thinking now being undertaken by bodies such as the Science Masters Association, H.M. Inspectorate of Schools, the Scottish Education Department, the professional scientific institutions and some of the larger industrial concerns. A full-time organizer will be appointed as a Nuffield Fellow to lead the work of each section. Each organizer will be backed by a small consultative committee, and detailed work on the programme will be undertaken by teams of practising teachers. The physics project will be started during the next few weeks under the leadership of Mr. D. McGill, who has been seconded for the purpose by the Scottish Education Department. The chairman of the Physics Consultative Committee will be Sir Nevill Mott. The intention is to complete the physics project within three years. In the first phase, the teams will concentrate on producing preliminary drafts of the required teachers' guides, class texts, and laboratory notes, and on commissioning demonstration and laboratory apparatus and visual aids for the course as a whole. The Associated Electrical Industries Film Unit and Design Unit have made their services available to the Committee for policies concerning visual aids. The second phase will comprise trying out the texts under classroom conditions and submitting them to further detailed criticism. In the final phase, arrangements will be made for the amended texts and approved versions of the apparatus and aids to be produced on a scale sufficient to meet the expected demand. Active steps are now being taken to begin work on the other four sections of the programme.

International Exchange of Skilled Persons

IN a written answer to a question in the House of Lords on March 19, Lord Hastings stated that full information about the United Nations Operational and Executive Personnel Scheme (OPEX) would be found in the report of the Secretary-General on programmes financed by the regular budget. The scheme was launched in January 1959, with an annual budget of 200,000 dollars, which was increased to 300,000 dollars for 1960, and to 850,000 dollars for 1961 and 1962. Up to September 1961, eighty posts had been established, of which seven were in the newer independent Commonwealth countries, three officers had completed their assignments and twenty-seven were in post. At their meeting in September 1960, the Commonwealth Economic Consultative Council decided that the best way to foster exchanges between Commonwealth countries of persons with specialized skills and experience would be for the Commonwealth Governments to improve their bilateral arrangements, and that appropriate arrangements should be devised, where they did not already exist, for filling executive as well as advisory, technical and specialized posts in Commonwealth countries which had recently achieved independence. Shortly after this decision was announced, Britain extended her offer of technical assistance to those Commonwealth countries which had recently become independent to including filling senior and important posts on the permanent establishment of the Governments of those countries, for a limited period, pending the training of a local successor. This offer was made to Ghana, Malaya, Nigeria and Sierra Leone, and so far about twenty appointments had been made, covering a wide variety of fields, including finance, engineering and telecommunications.

British Student Population

IN a written answer in the House of Commons on March 27, Sir Edward Boyle stated that of 15,256 students in arts, science and technology in 1952, 16·7 per cent left, for various reasons, without success, 1,688 leaving for academic reasons; for 1955, corresponding figures were 18,239, 13·9 per cent and 1,804; and for 1957, 21,793, 14·3 per cent and 2,584. Sir Edward also stated that a target of 150,000 students for the next five years had been selected to provide the greatest practicable opportunities for the large age-groups reaching university age in 1966–67; it would provide university places for as high a proportion as was available at present.

British Colleges of Technology

IN answer to a question in the House of Commons on March 28, the Secretary of State for Scotland, Mr. J. Maclay, said that of the Government's programme of technical college building to be started by the end of March 1964, projects had been started to date to the value of £13·5 million, including projects already completed to the value of £1 million and others to the value of £1·5 million expected to be completed by the end of 1962. In a written answer on March 26 the Minister of Education, Sir David Eccles, stated that twenty-one colleges were at present recognized as regional colleges of further education and he was reviewing the list in consultation with the regional advisory councils for further education. Seventeen of these were included in the first list compiled in 1956 and four were added between 1956 and 1959; one, the Brunel College of Technology, was being designated a college of advanced technology on April 1. In October 1960, 10,280 students were enrolled in full-time and 2,943 in sandwich courses, and of these, 4,270 and 2,767 were in advanced courses. There were also 33,077 part-time day and 43,527 evening students, and of these, 7,415 and 7,029, respectively, were in advanced courses.

Approach to a National Library in England

R. Irwin, director, School of Librarianship and Archives, University College, London, contributes to the *Library Association Record* (March 1962) an article, "The Approach to a National Library in England", which is of some general interest. Mr. Irwin describes briefly, but lucidly, the various steps by which something of a national library system was built up and the early background to such efforts, notably in the late sixteenth and early seventeenth centuries. Due attention is given to the relation of such developments to the advance of science itself. The scientist should find Mr. Irwin's article of special interest, though he takes the record no further than the founding of the Science Museum in 1857.

Library Services in Manchester

The one hundred and ninth annual report of the Libraries Committee of the City of Manchester, covering the year ended March 31, 1961, records a stock of 1,162,952 volumes at the end of the year, 162,387 volumes being added and 164,169 withdrawn (Pp. 38 + 4 plates. Manchester: The Public Libraries, 1962). Issues decreased by 316,502 to 6,985,430, but reference library issues again increased, by 95,467, to 1,829,225. Concern is again expressed over the dilution and turn-over of staff; of 276 full-time staff, 54 resigned during the year, bringing the total of resignations in the past five years to 256. In his report, the City Librarian notes the concentration of photographic services in a single unit and the steadily increasing demand for photocopies. Consolidation continued in the Technical Library, in which items issued for reference increased by 51,312 to 873,772, although issues from stock decreased by 30 per cent. In its first full year of operation the Patents and Microtexts Library served 15,010 readers, consulting 119,436 patent specifications, 3,179 microfilms and 717 microcards, while the Technical Information Service issued 1,940 items and handled 14,004 telephone and 598 telex inquiries. Accounts of the numerous other aspects of the work of the Manchester Public Libraries are included in the report.

The Smithsonian Institution

The annual report of the Smithsonian Institution, the United States National Museum, for 1961 adheres in general format to previous years and records extensive building operations (Pp. viii + 188. Washington, D.C.: Government Printing Office, 1961). An extension to the east wing and air conditioning of the existing Natural History Department is in progress and the corner-stone of the Museum of History and Technology was laid in May 1961. It is anticipated that this Museum will be completed in July 1962, and that it will commemorate the national heritage and illustrate the historical development of the basic elements in the life of the country. Original objects associated with famous Americans and historical events include the original Star-Spangled Banner and the desk at which Jefferson drafted the Declaration of Independence. The history of science and technology will be traced in exhibits of the original apparatus of the scientists, relating their great discoveries to the machines in which the inventors and engineers applied new scientific knowledge for the benefit of the community. It is satisfactory to record that ample provision is being made for the conservation of the objects in the Museum.

Protection of Nature: South Downs

The National Parks Commission has issued designation orders to make the South Downs in Sussex and Hampshire, from Beachy Head to Winchester, an area of outstanding natural beauty (*Intelligence Unit. Council for Nature Press Bull.* 25). The orders are subject to confirmation by the Minister of Housing and Local Government. The Forestry Commission has leased to the Yorkshire Naturalists Trust twelve acres of the famous Grass Wood near Grassington in Wharfedale. This wood, once famous as a site for the rare lady's slipper orchid, is an ashwood on limestone, and has been visited by generations of Yorkshire naturalists.

Hayley Wood

The Cambridgeshire and Isle of Ely Naturalists' Trust has taken an option to buy the 122-acre Hayley Wood, the largest unspoilt boulder-clay wood remaining in the country, ten miles west of Cambridge. This type of woodland is famous for its displays of spring flowers, including wood anemones, dog violets, early purple orchids, bluebells, and instead of the more usual primroses, oxlips, for which this part of the eastern counties is famous. The Trust is appealing for £7,500 to buy the wood and establish a fund to enable the traditional system of management to be maintained.

Downe

Charles Darwin's Orchid Bank at Downe in Kent has recently been acquired as a nature reserve by the Kent Naturalists' Trust. It is a site of great scientific interest which shows a wide range of vegetation types including ancient chalk grassland with a very rich flora; and, as it is only sixteen miles from the centre of London, the need for conservation is urgent and considerable. It is also of unique historical importance, for Darwin is known to have carried out field studies there from his nearby home, Down House, where he lived for forty years. The reserve is eleven acres in extent, and in addition to chalk grassland, it includes chalk scrub with juniper (now rare in Kent) and beechwood on chalk; and where clay-with-flints overlies the chalk is a strip of woodland with oak, beech and hornbeam. Eleven of the thirteen species of orchid mentioned by Darwin as occurring within a mile of his house can still be found in the reserve; and in addition *Aceras anthropophorum*, not included in his list, has recently been found there. The bryophyte flora is also of interest. The Trust has set up a management committee to organize necessary conservation measures; these include fencing (a form of chestnut paling traditional in Kent is being used) and the cutting back of scrub which is invading the grassland. This committee is also preparing a long-term scientific programme of ecological observation.

Steel Foundry Year

The British Steel Founders' Association has announced that open days will be held to mark Steel Foundry Year by the following members of the Association: Catton and Co., Ltd., Leeds (May 23); Head Wrightson Steel Foundries, Ltd., Thornaby-on Tees (May 24); F. H. Lloyd and Co., Ltd. (May

30–June 1); Edgar Allen and Co., Ltd., and Hadfields, Ltd., Sheffield (June 21); Brown, Lenox and Co., Ltd., Pontypridd (July 4); English Steel Castings Corporation, Ltd., Sheffield (July 5); Stewarts and Lloyds, Ltd., Glasgow (September 20); Osborn Foundry and Engineering Co., Ltd., Sheffield (September 21). A conference will also be held in London on May 10. Further information can be obtained from Mr. K. V. Robinson, British Steel Founders' Association, 13 Broomgrove Road, Sheffield 10.

Selby Fellowship

The Selby fellowship has been established by the Australian Academy of Science to bring graduates of high promise and proved capacity for research to work in the laboratories of universities or research institutions in Australia. The fellowship may be awarded in any branch of physical or biological science and is tenable at any university or research institution in Australia, normally for one full year of work. Candidates must have taken their first university degree, and have had preliminary research experience, at some university or universities in a country other than Australia. In general, they should hold a Ph.D. degree or have equivalent status and experience, but the fellowship will not normally be given to those who have already held a senior research award. Applicants should be less than thirty years of age on July 1 in the year in which their applications are received. The fellowship will carry a stipend of £2,000 (Australian) per annum. The costs of the Fellow's travel to Australia, and back to his country of origin at the conclusion of the fellowship, will be provided, up to a limit of £A500, including dependants, if any. Applications should be sent to the Assistant Secretary, Australian Academy of Science, Gordon Street, Canberra City, A.C.T., before July 30.

The Night Sky in May

New moon occurs on May 4d. 04h. 25m. U.T. and full moon on May 19d. 14h. 32m. The following conjunctions with the Moon take place: May 1d. 19h., Mars 3° N.; May 6d. 00h., Aldebaran 1° S.; May 12d. 06h., Regulus 1° S.; May 25d. 03h., Saturn 0·6° S.; May 27d. 04h., Jupiter 2° N.; May 30d. 15h., Mars 4° N. In addition to these conjunctions with the Moon, Venus is in conjunction with Aldebaran on May 6d. 18h., Venus being 6° N., and Mercury with Aldebaran on May 10d. 10h., Mercury being 8° N. Mercury is well placed for observation during the first three weeks of May, when it is visible low in the west after sunset, setting about 2 hr. after the Sun. Venus is an evening star, visible in the west after sunset. It sets at 21h. 35m., 22h. 15m. and 22h. 40m. on May 1, 15 and 31, respectively; its stellar magnitude is $-3·3$. Its distance decreases during the month from 142 to 127 million miles and the visible portion of the apparent disk decreases from 0·918 to 0·847. Mars is too close to the Sun for observation. Jupiter rises at 2h. 50m., 1h. 50m. and 0h. 55m. at the beginning, middle and end of the month, respectively. It is in Aquarius, its stellar magnitude is $-1·9$ and its distance from the Earth in the middle of the month is 480 million miles. Saturn is in Capricornus, rising at 1h. 50m , 0h. 55m. and 23h. 55m. on May 1, 15 and 31, respectively. Its stellar magnitude is $+0·8$ and its distance from the Earth on May 15 is 900 million miles. There are no occultations of stars brighter than magnitude 6 visible at Greenwich. Comet Seki-Lines (1962c) will have faded to magnitude 8 by early May, and to magnitude 11 by the end of May.

Announcements

Sir Harold Jeffreys, formerly Plumian professor of astronomy in the University of Cambridge, and Fellow of St. John's College, Cambridge, has been granted the Grove Karl Gilbert Award in Seismic Geology by the Carnegie Institution of Washington to carry out a programme of correcting his long standard "Travel-time tables".

Mr. F. P. Doyle has been elected to the Board of Directors of the Beecham Research Laboratories, Ltd., as research director. Mr. Doyle succeeds Dr. J. Farquharson, who relinquishes his post on medical advice. Dr. Farquharson will later take up an appointment as special consultant directly responsible to the research director, Beecham Group, Ltd.

The annual general meeting of the American Philosophical Society will be held in Philadelphia during April 26–28. Further information can be obtained from the Secretary, American Philosophical Society, 104 South Fifth Street, Philadelphia.

An international conference on "Instrumentation for High Energy Physics", sponsored by the International Union of Pure and Applied Physics, will be held at CERN, Geneva, during July 16–18. Further information can be obtained from Mr. E. W. D. Steel, Scientific Conference Secretariat, CERN, Geneva 23.

A special meeting, arranged by the Iron and Steel Institute, will be held in Germany during June 27–July 11. The main meeting will be held in Dusseldorf during July 1–8, and there will be special excursions to Saarland and Trier, to Heidelberg and Frankfurt/Main, and to Salzgitter and Bremen. Further information can be obtained from the Secretary, the Iron and Steel Institute, 4 Grosvenor Gardens, London, S.W.1.

The Industrial Safety Division of the Royal Society for the Prevention of Accidents is organizing a conference with the theme "Safety by Research", which will be held in Blackpool during May 10–13. The programme will include: publicizing the results of safety research; safety at work: the trade union point of view; a new look at accident prevention and its implication for practice; the development and influence of British standards on safety. There will also be an exhibition of industrial safety equipment. Further information can be obtained from the Royal Society for the Prevention of Accidents, Industrial Safety Division, Terminal House, 52 Grosvenor Gardens, London, S.W.1.
